Cancer Genomics

Brief review of cancer fundamentals,
What is cancer and what causes it?

Mining Cancer Genomic Data

Hands-on analysis to identify genomic changes in different cancers and identify new targets for therapy

Towards personalized cancer treatments

Recap on how the immune system normally detects cancer cells and how we can predict mutations that can be recognized by T cells

Cancer Immunoinformatics

Hands-on analysis to design personalized cancer vaccines

What is Cancer?

“Cancer is a name given to a collection of related diseases, where some of the body’s cells begin to divide without stopping and spread into surrounding tissue”

Source: <https://www.cancer.gov>

It is estimated that cancer will strike 40% of people at some point in their lifetime with frequently devastating effects.

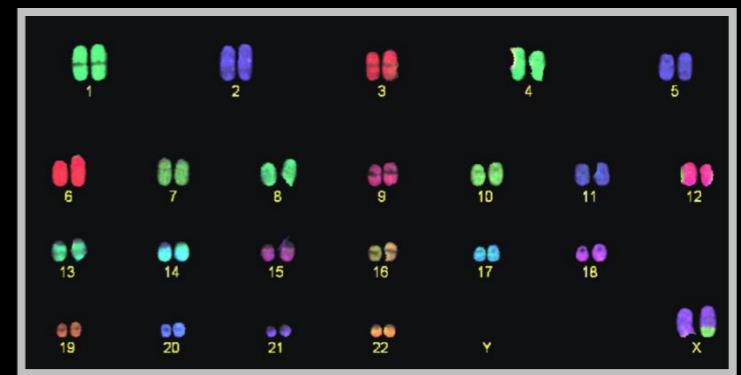

What is Cancer?

“Cancer is a name given to a collection of related diseases, where some of the body’s cells begin to divide without stopping and spread into surrounding tissue”

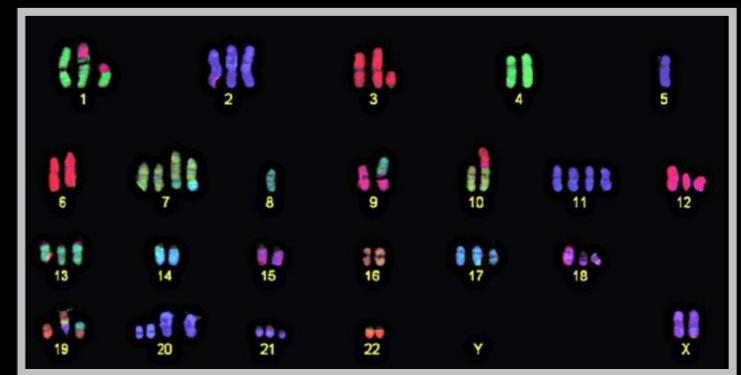

Source: <https://www.cancer.gov>

Cancer is a disease of the Genome

- Caused by changes to genes that control the way our cells function, especially how they **grow and divide**.
- A major challenge in treating cancer is that every tumor is different: Each person's cancer has a unique combination of genetic changes (both “driver” & “passenger”).
- As the cancer continues to grow, additional changes will occur.

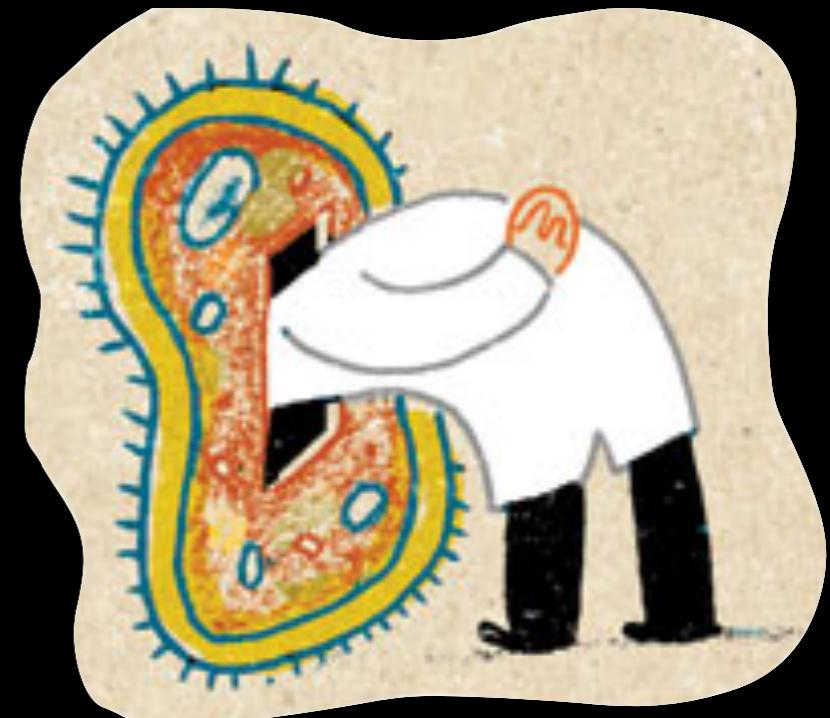

Healthy 46 chromosomes

Example cancer 59 chromosomes

Goals of Cancer Genome Research

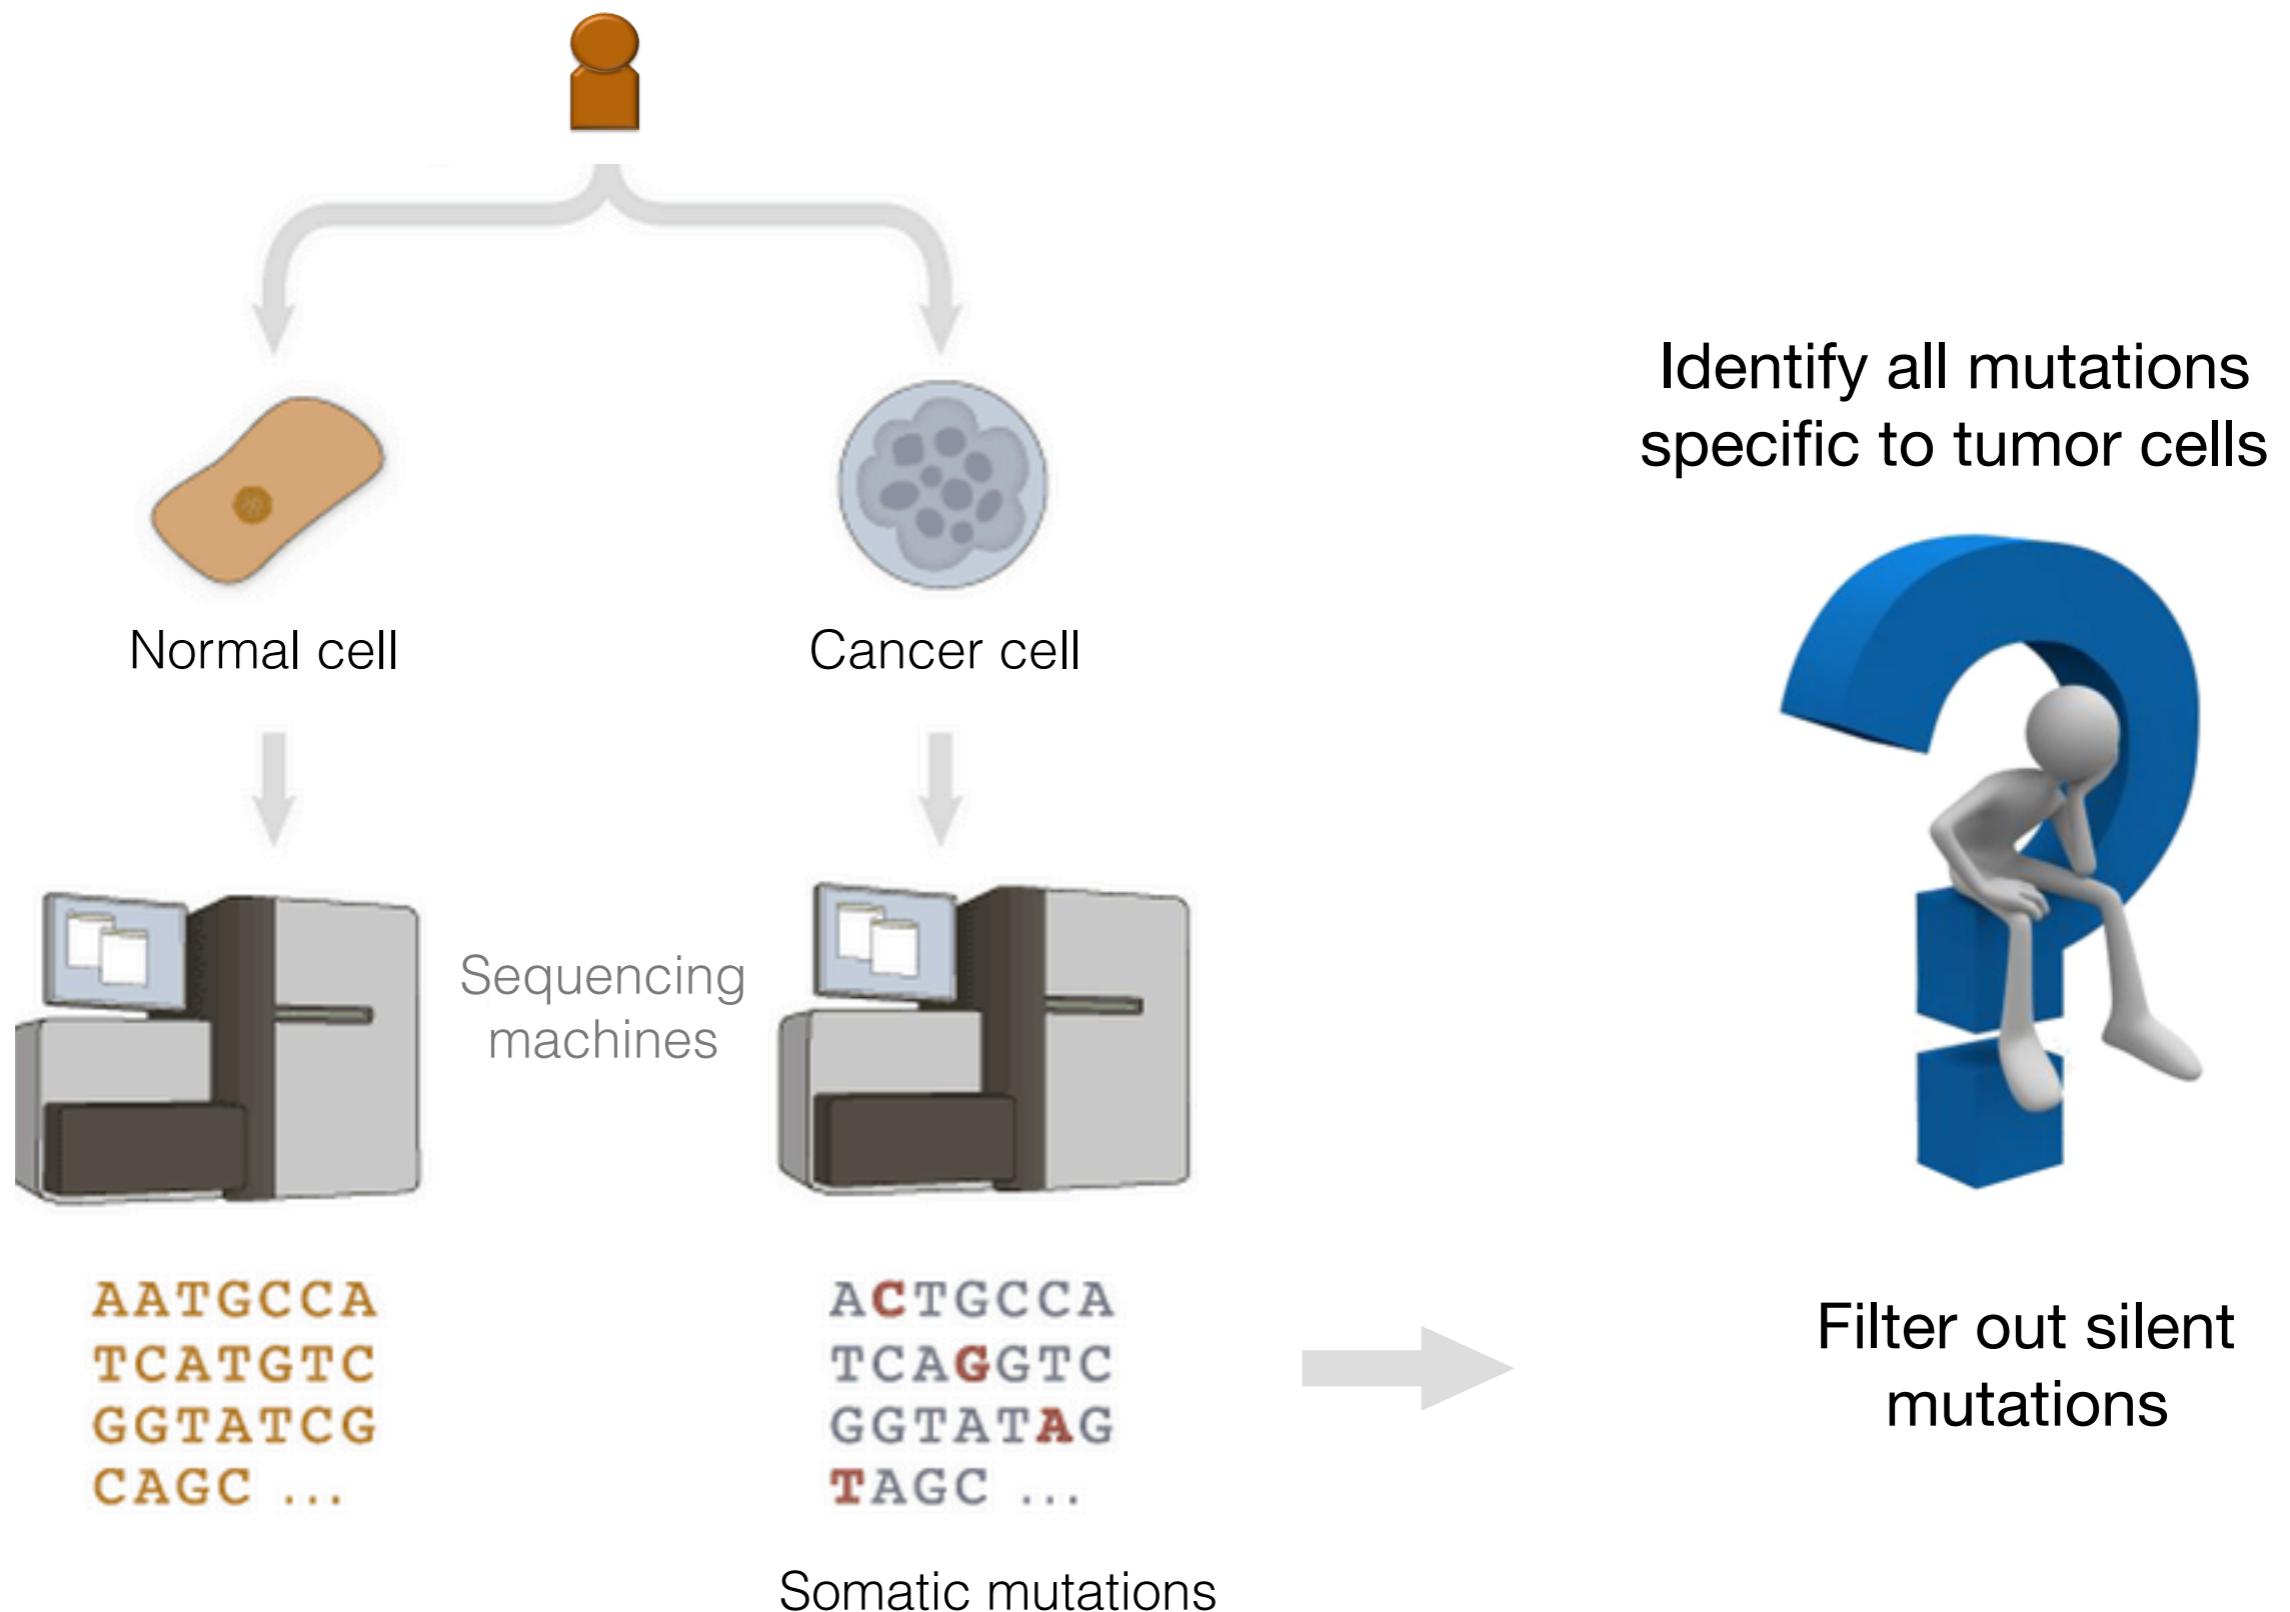

- Identify changes in the genomes of tumors that drive cancer progression
- Identify new targets for therapy
- Select drugs based on the genomics of the tumor
- Provide early cancer detection and treatment response monitoring
- Utilize cancer specific mutations to derive neoantigen immunotherapy approaches

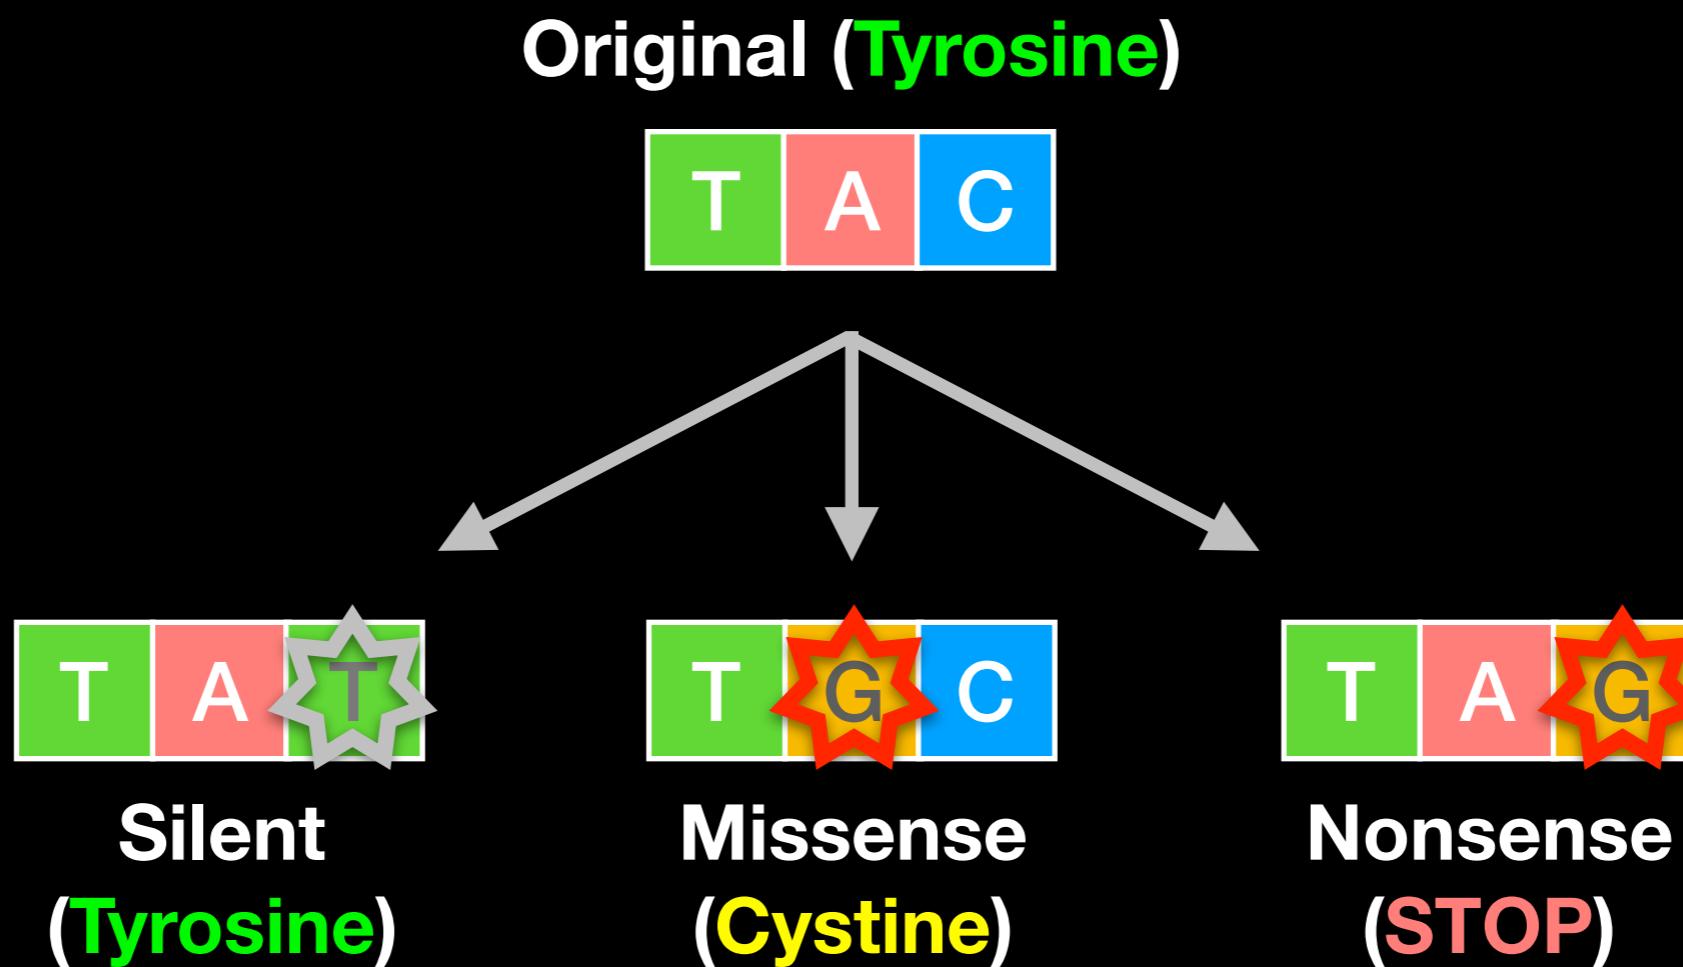

Finding Cancer Drivers

Finding Cancer Associated Mutations

Mutations detected: Point mutations

Mutations detected: Indels

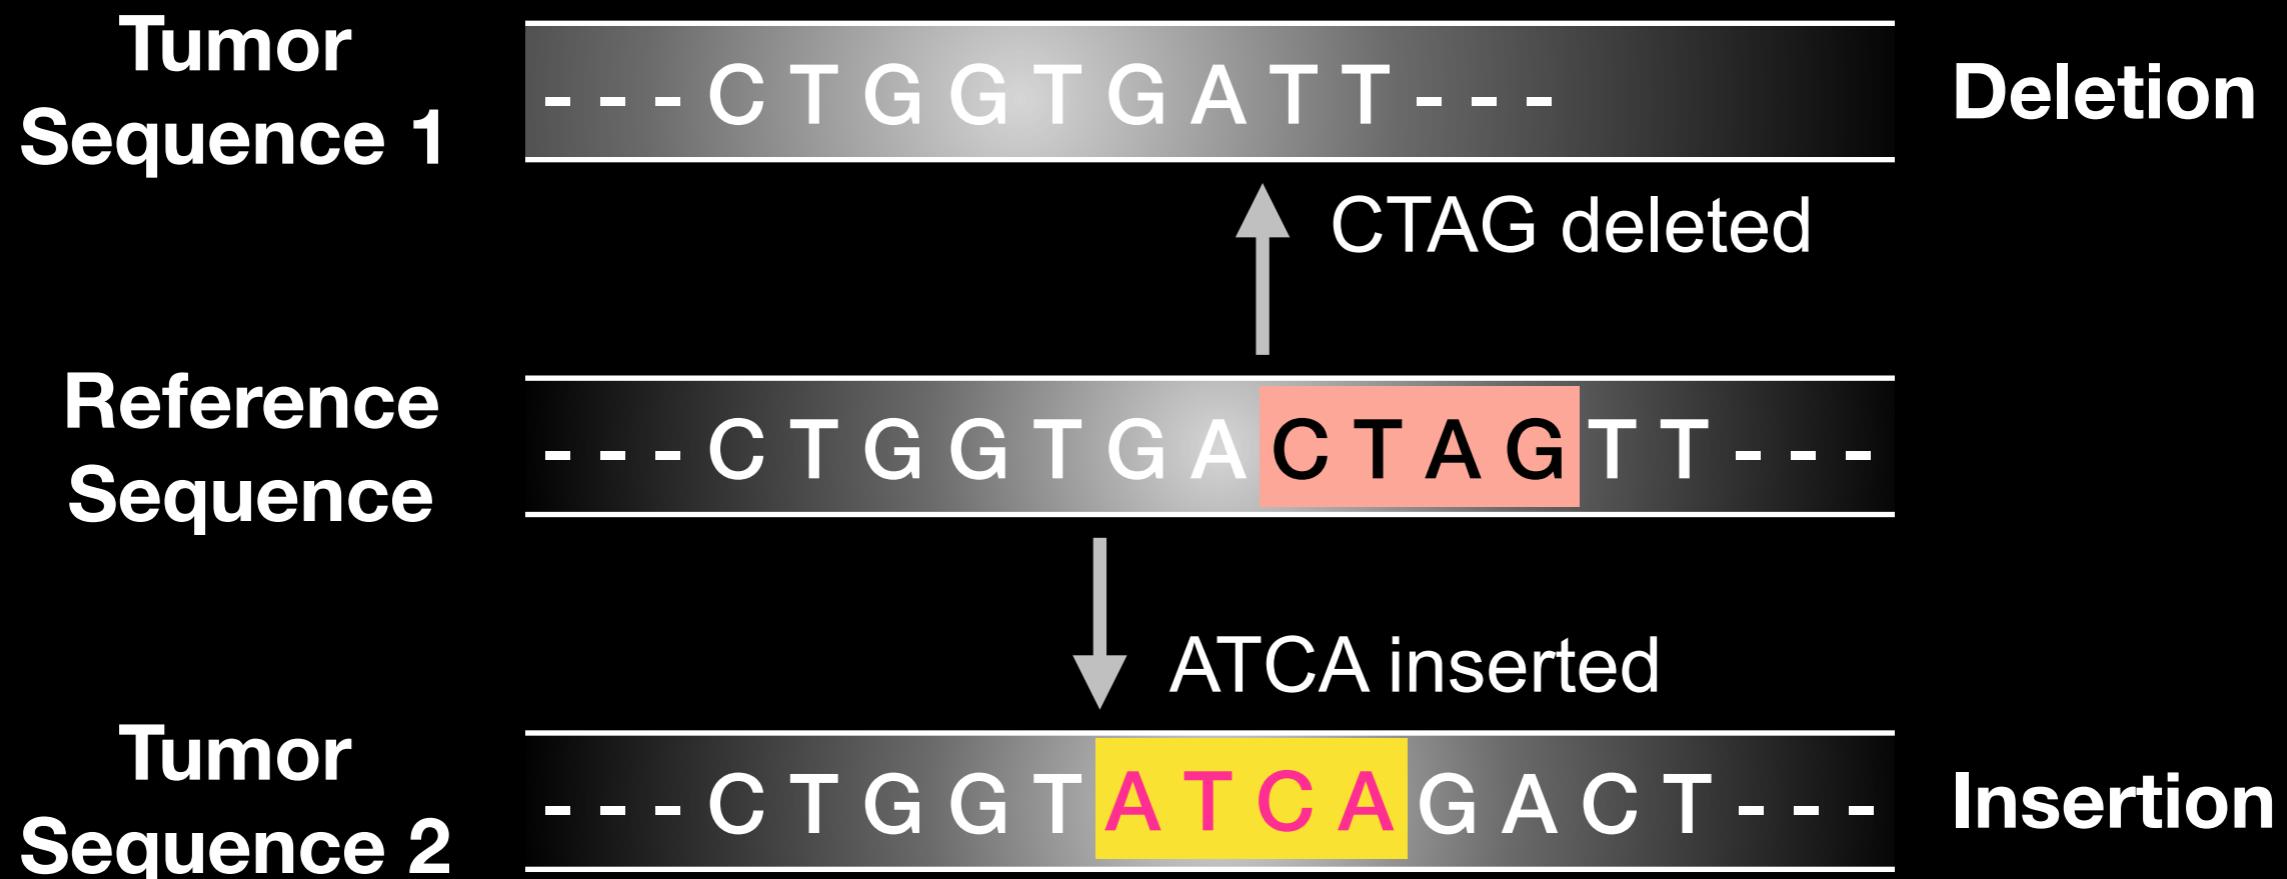

Reference
Sequence

--- C T G G T G A C T A G T T ---

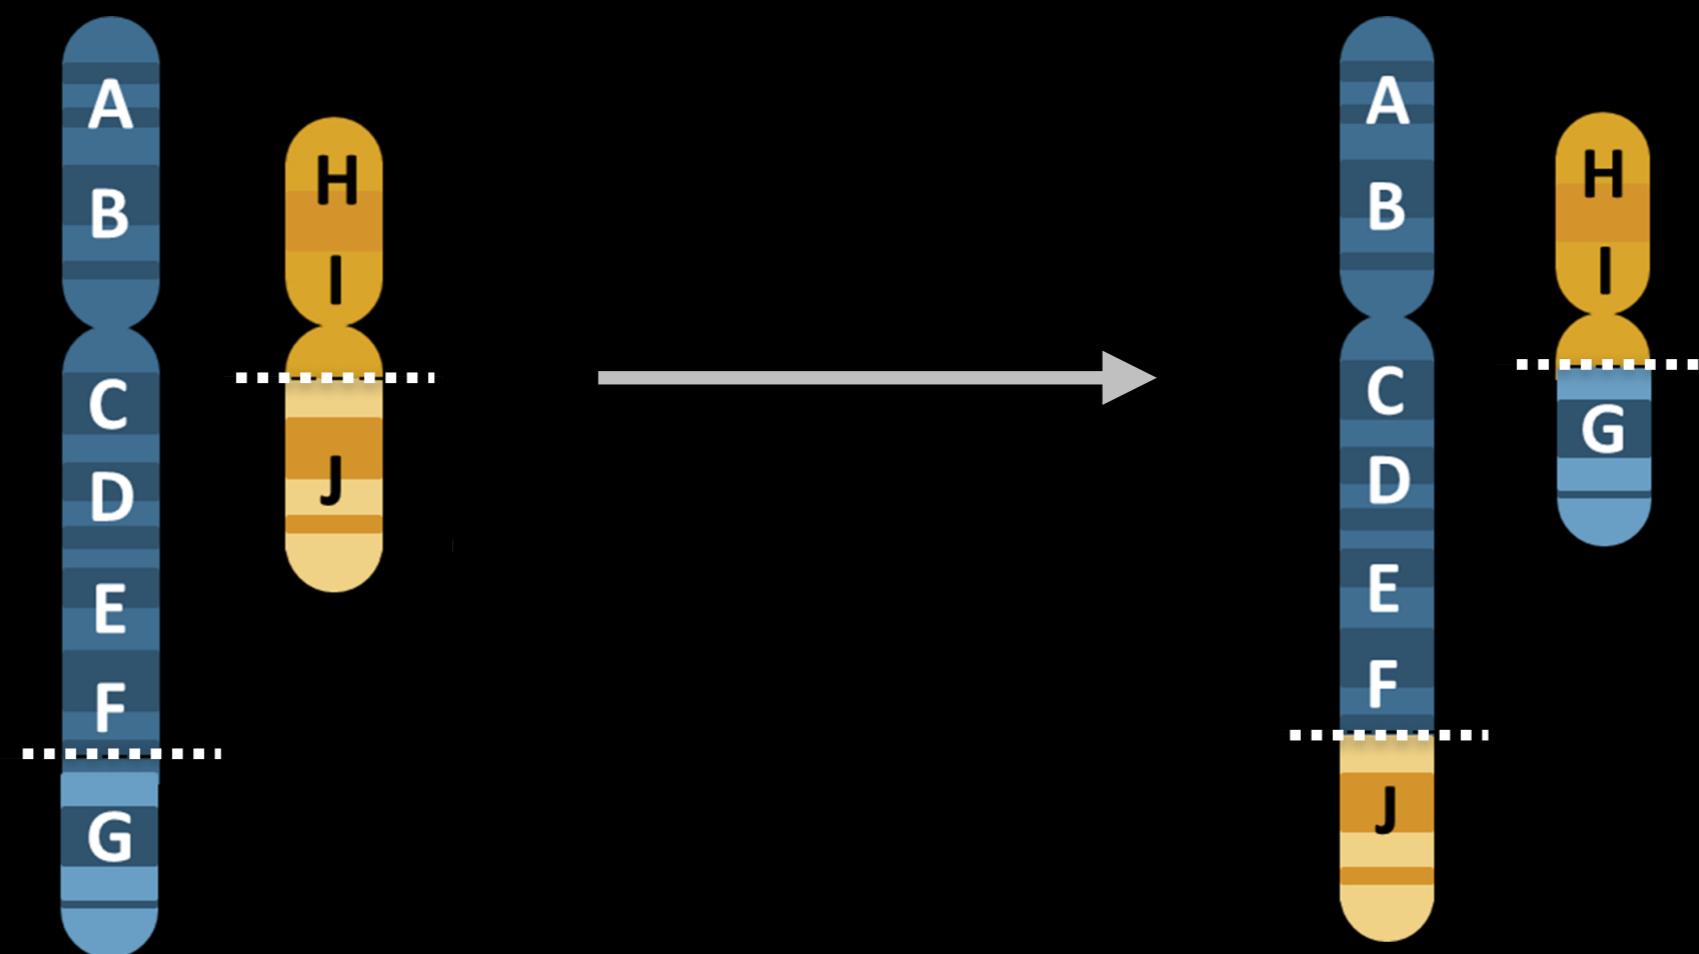

Mutations detected: Indels

The diagram illustrates a deletion mutation. On the left, 'Tumor Sequence 1' is shown as a grey box containing the sequence:
- - - C T G G T G A T T - - -
On the right, 'Deletion' is written above the word 'CTAG'. In the center, a white arrow points upwards from the sequence, indicating the deletion of the four nucleotides 'CTAG'. Below this, the 'Reference Sequence' is shown as a black box with a red highlighted region:
- - - C T G G T G A **CTAG** T T - - -
The red box highlights the deleted sequence 'CTAG'.

Mutations detected: Indels

Mutations detected: Translocations

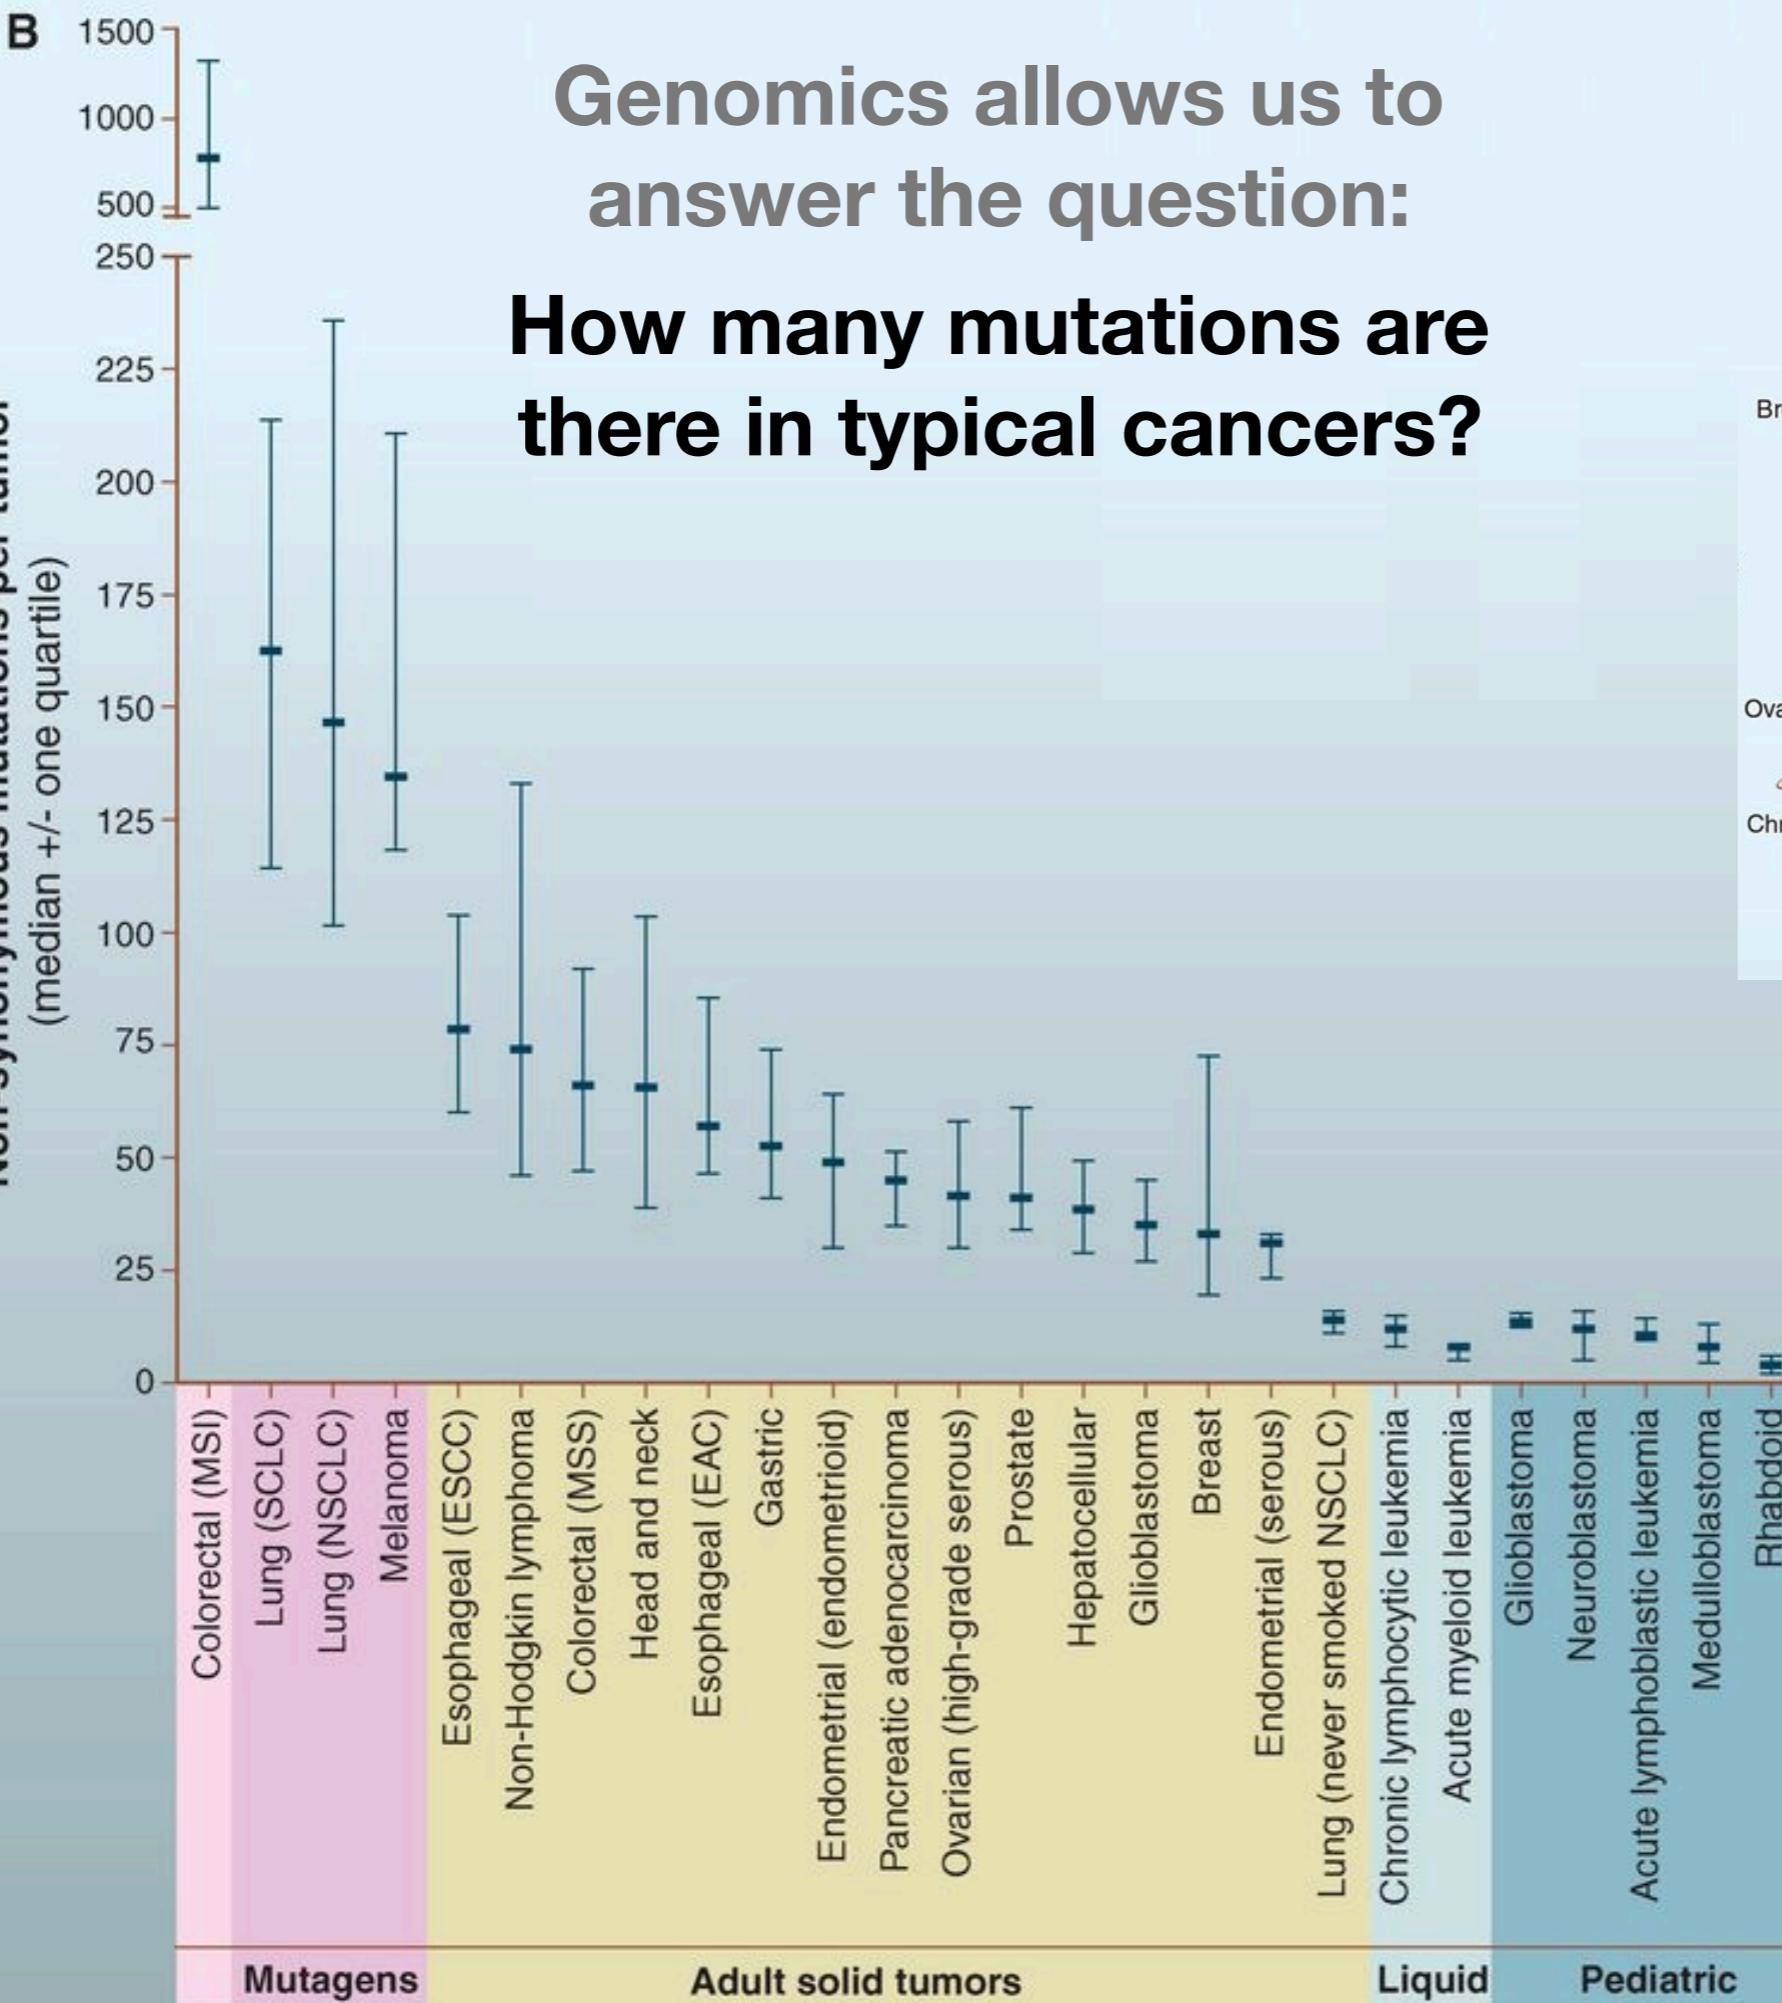

What can go wrong in cancer genomes?

Type of change	Some common technology to study changes
DNA mutations	WGS, WXS
DNA structural variations	WGS
Copy number variation (CNV)	CGH array, SNP array, WGS
DNA methylation	Methylation array, RRBS, WGBS
mRNA expression changes	mRNA expression array, RNA-seq
miRNA expression changes	miRNA expression array, miRNA-seq
<i>Protein expression</i>	Protein arrays, mass spectrometry

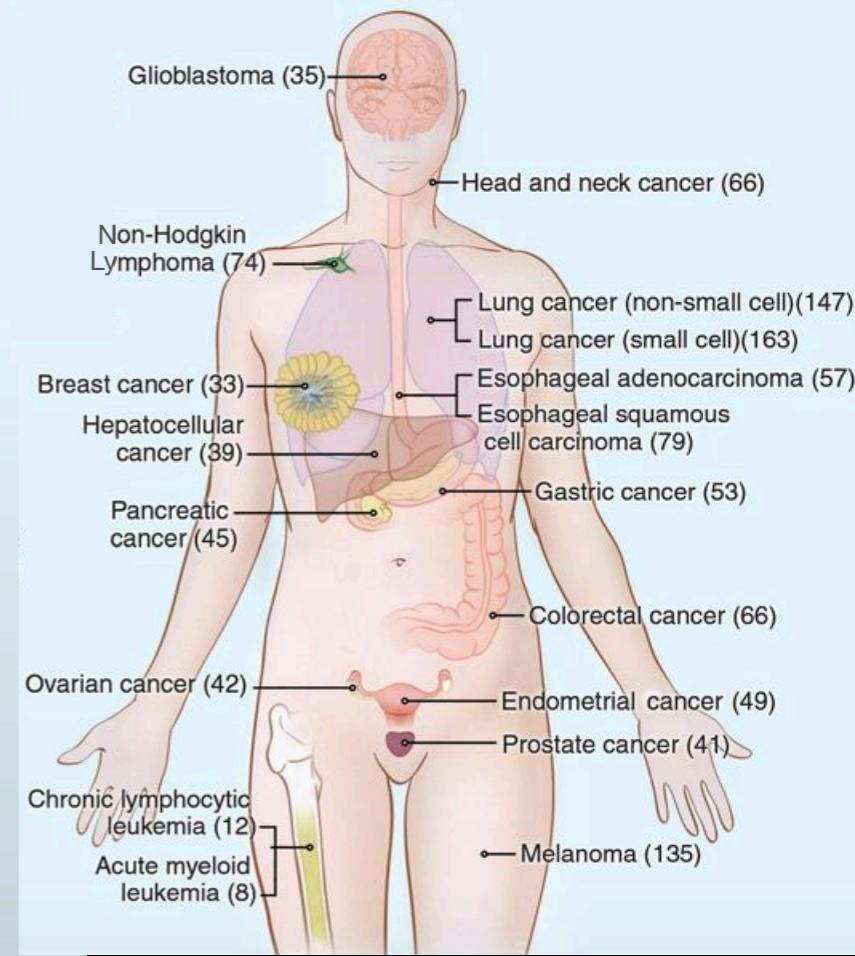

WGS = whole genome sequencing, WXS = whole exome sequencing

RRBS = reduced representation bisulfite sequencing, WGBS = whole genome bisulfite sequencing

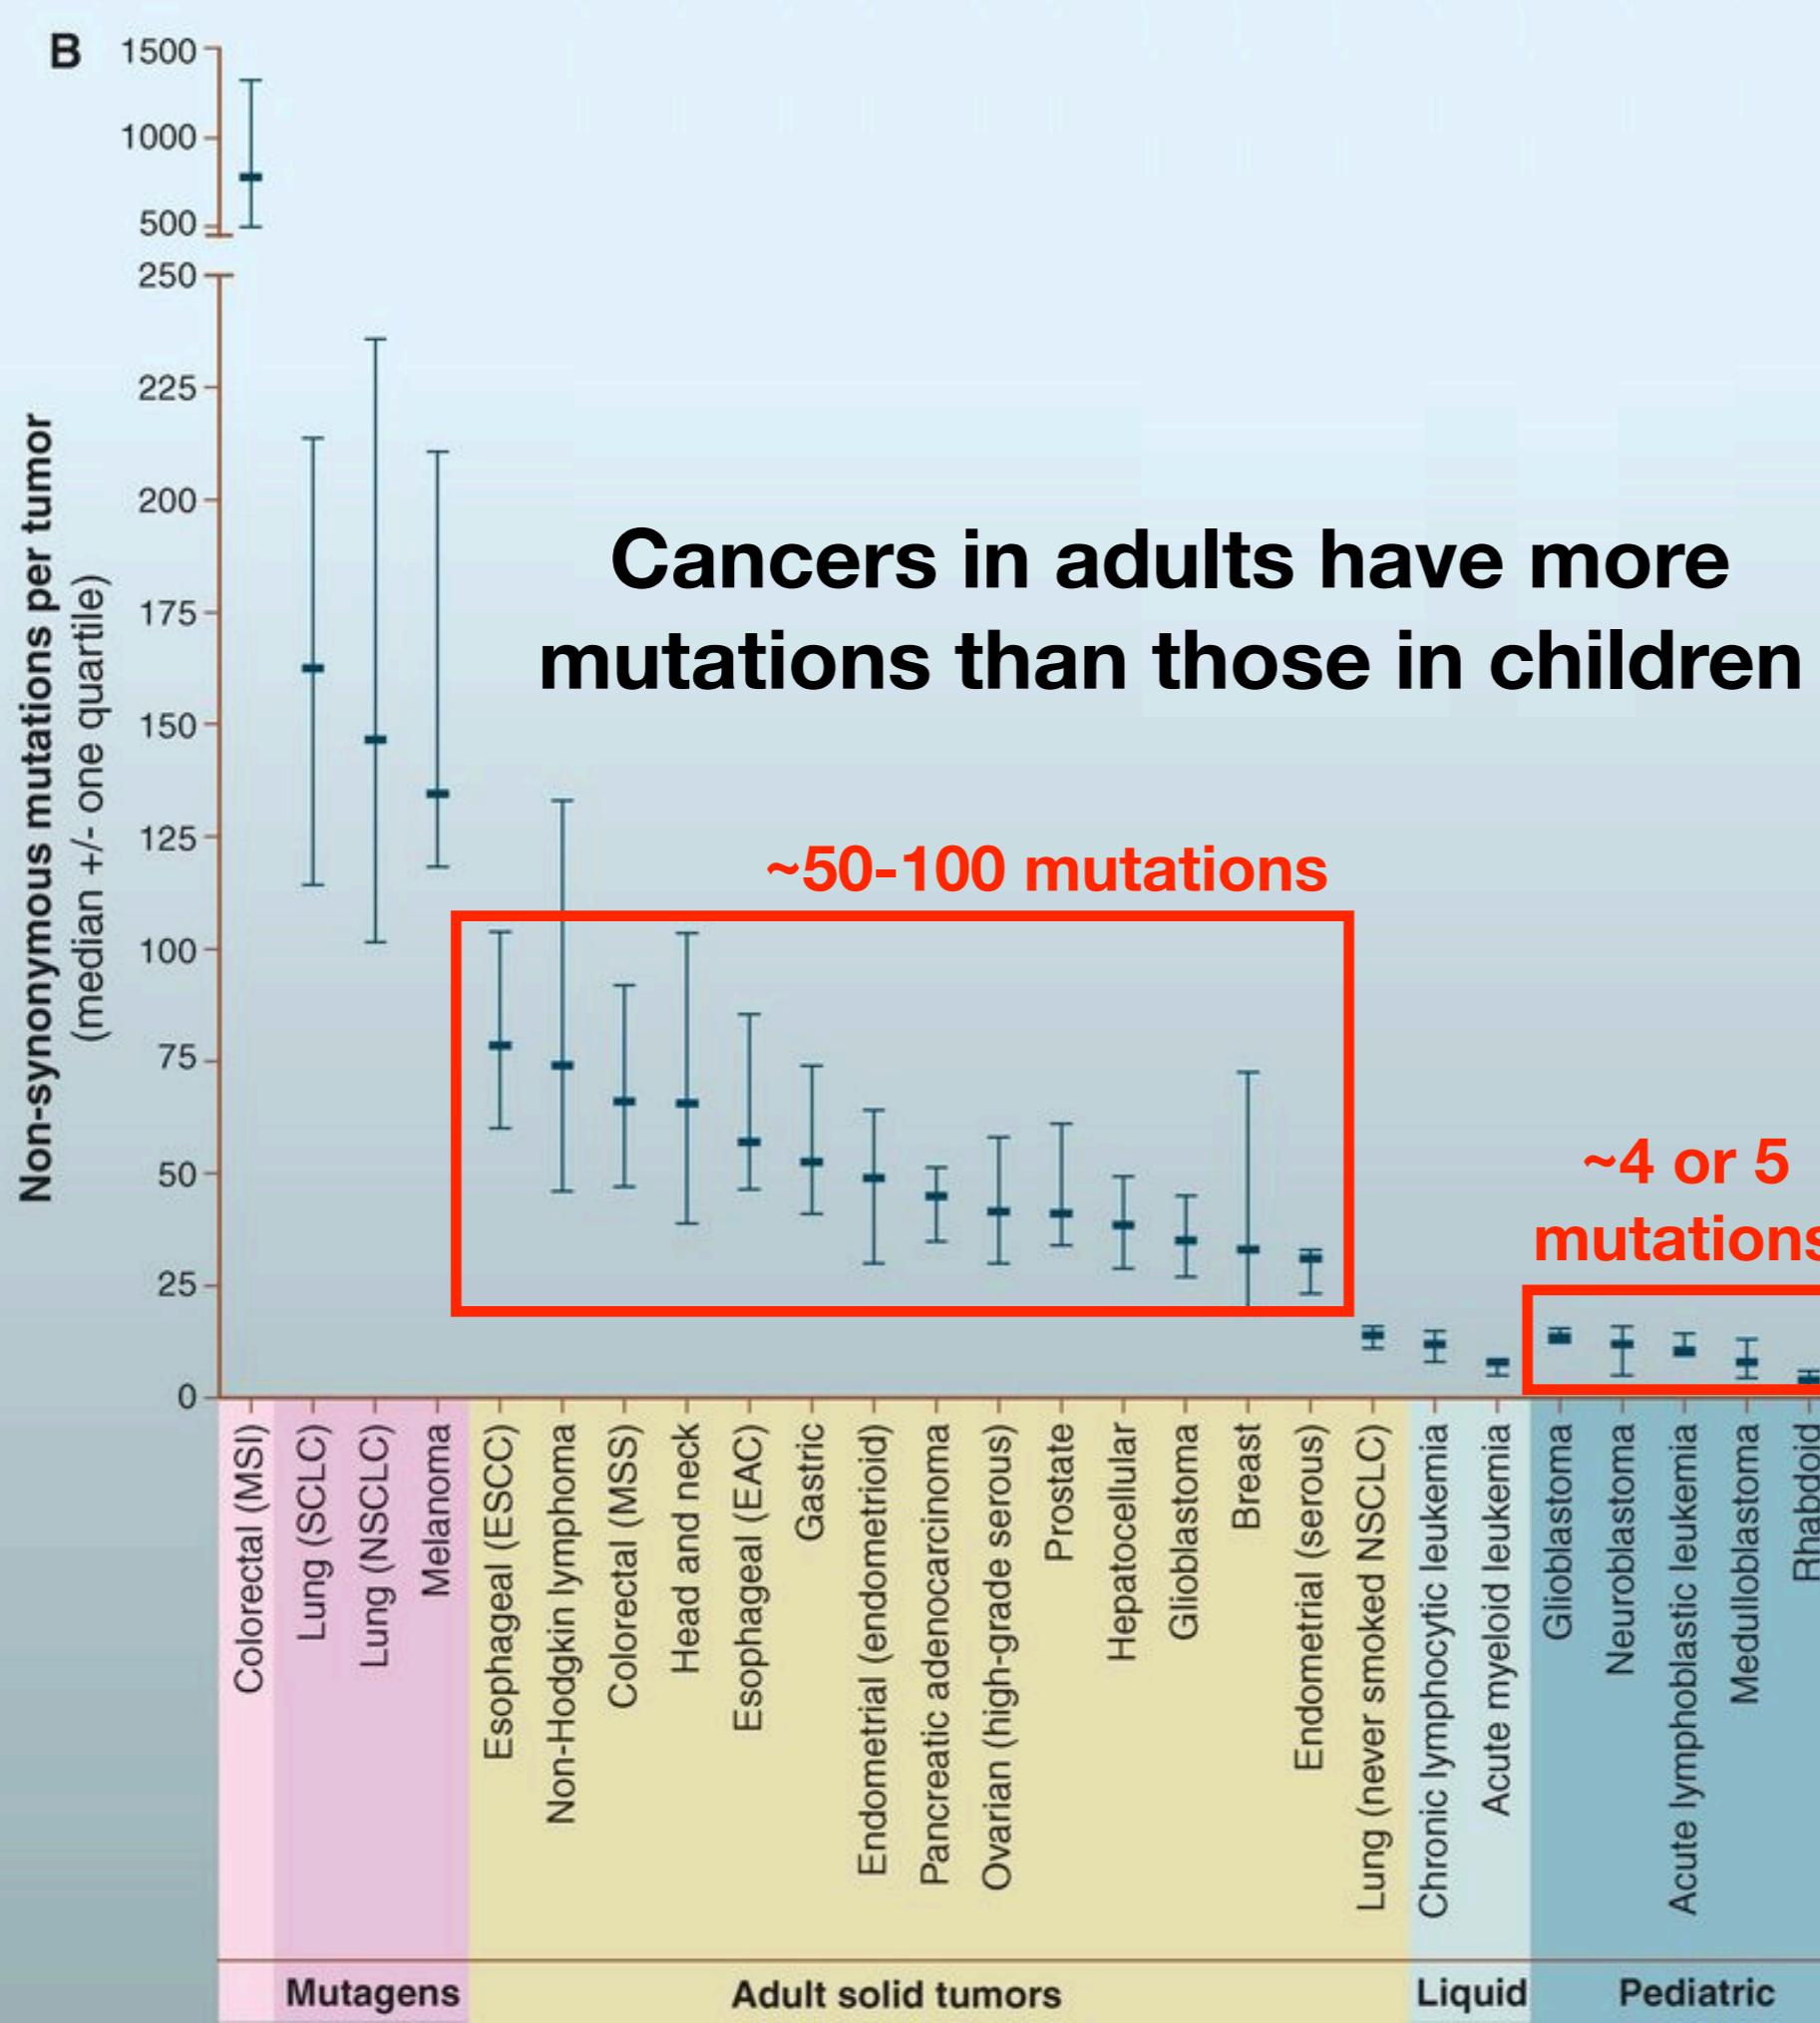

Genomics allows us to answer the question:

How many mutations are there in typical cancers?

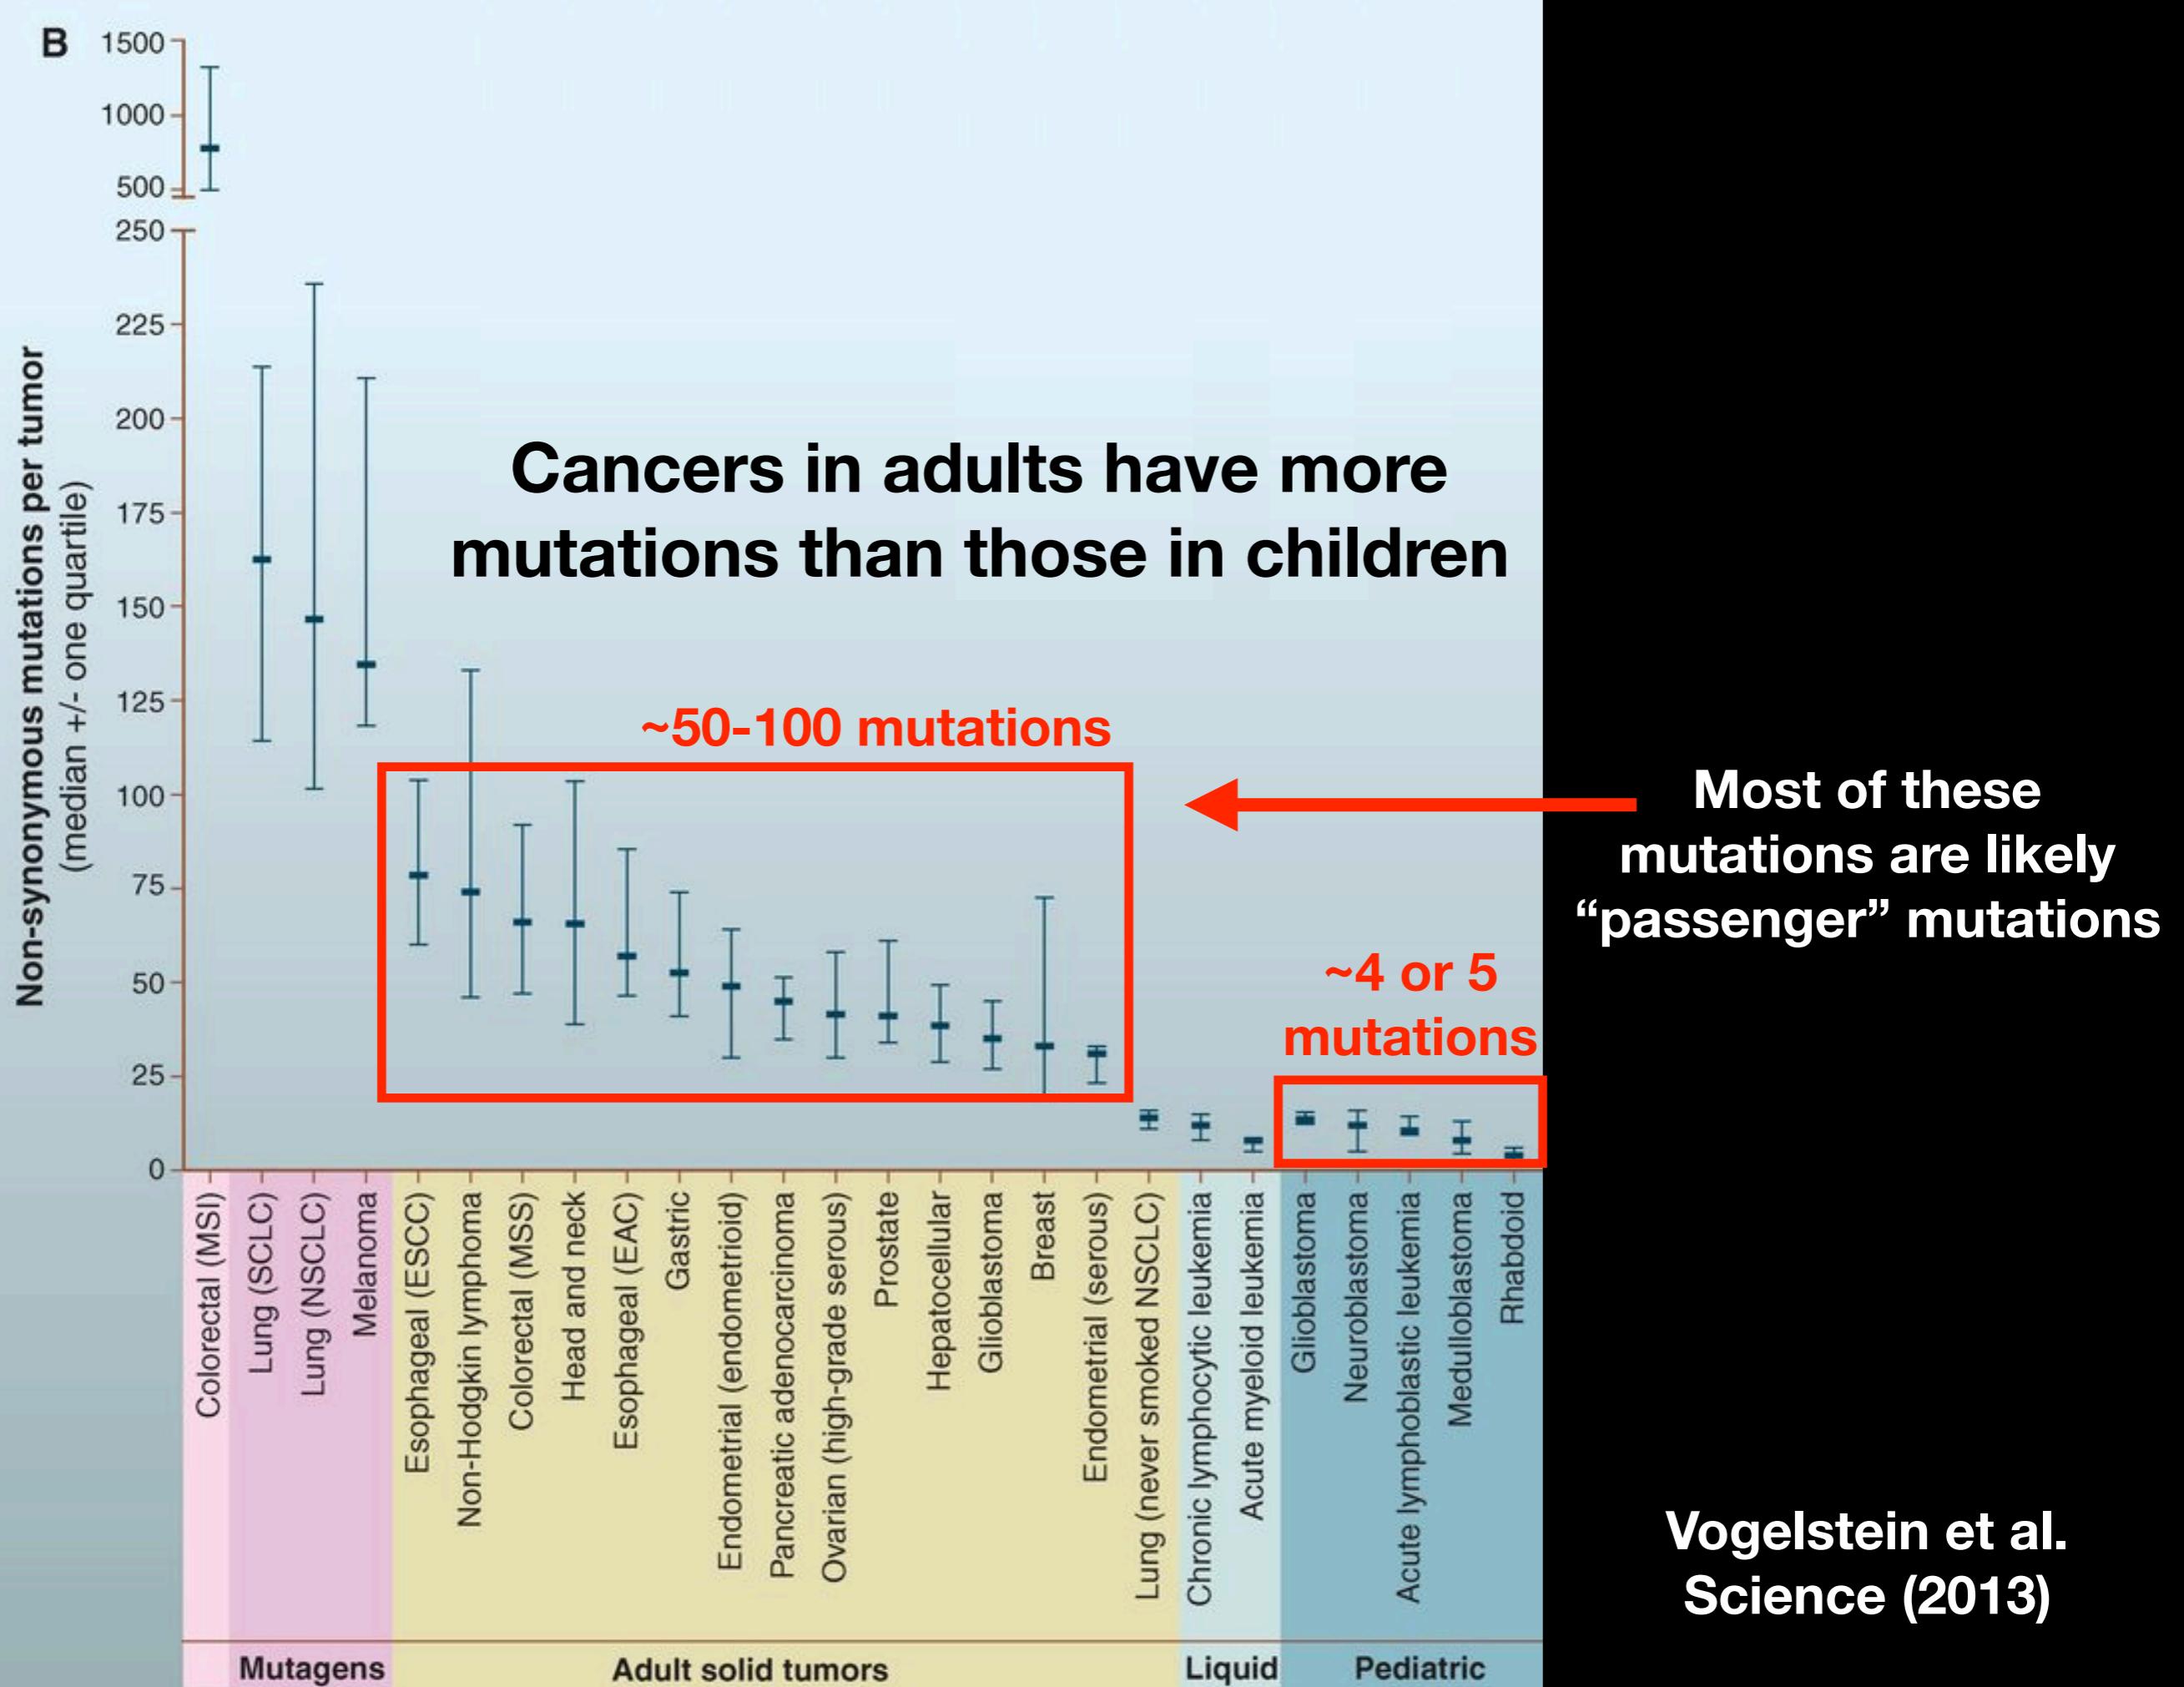

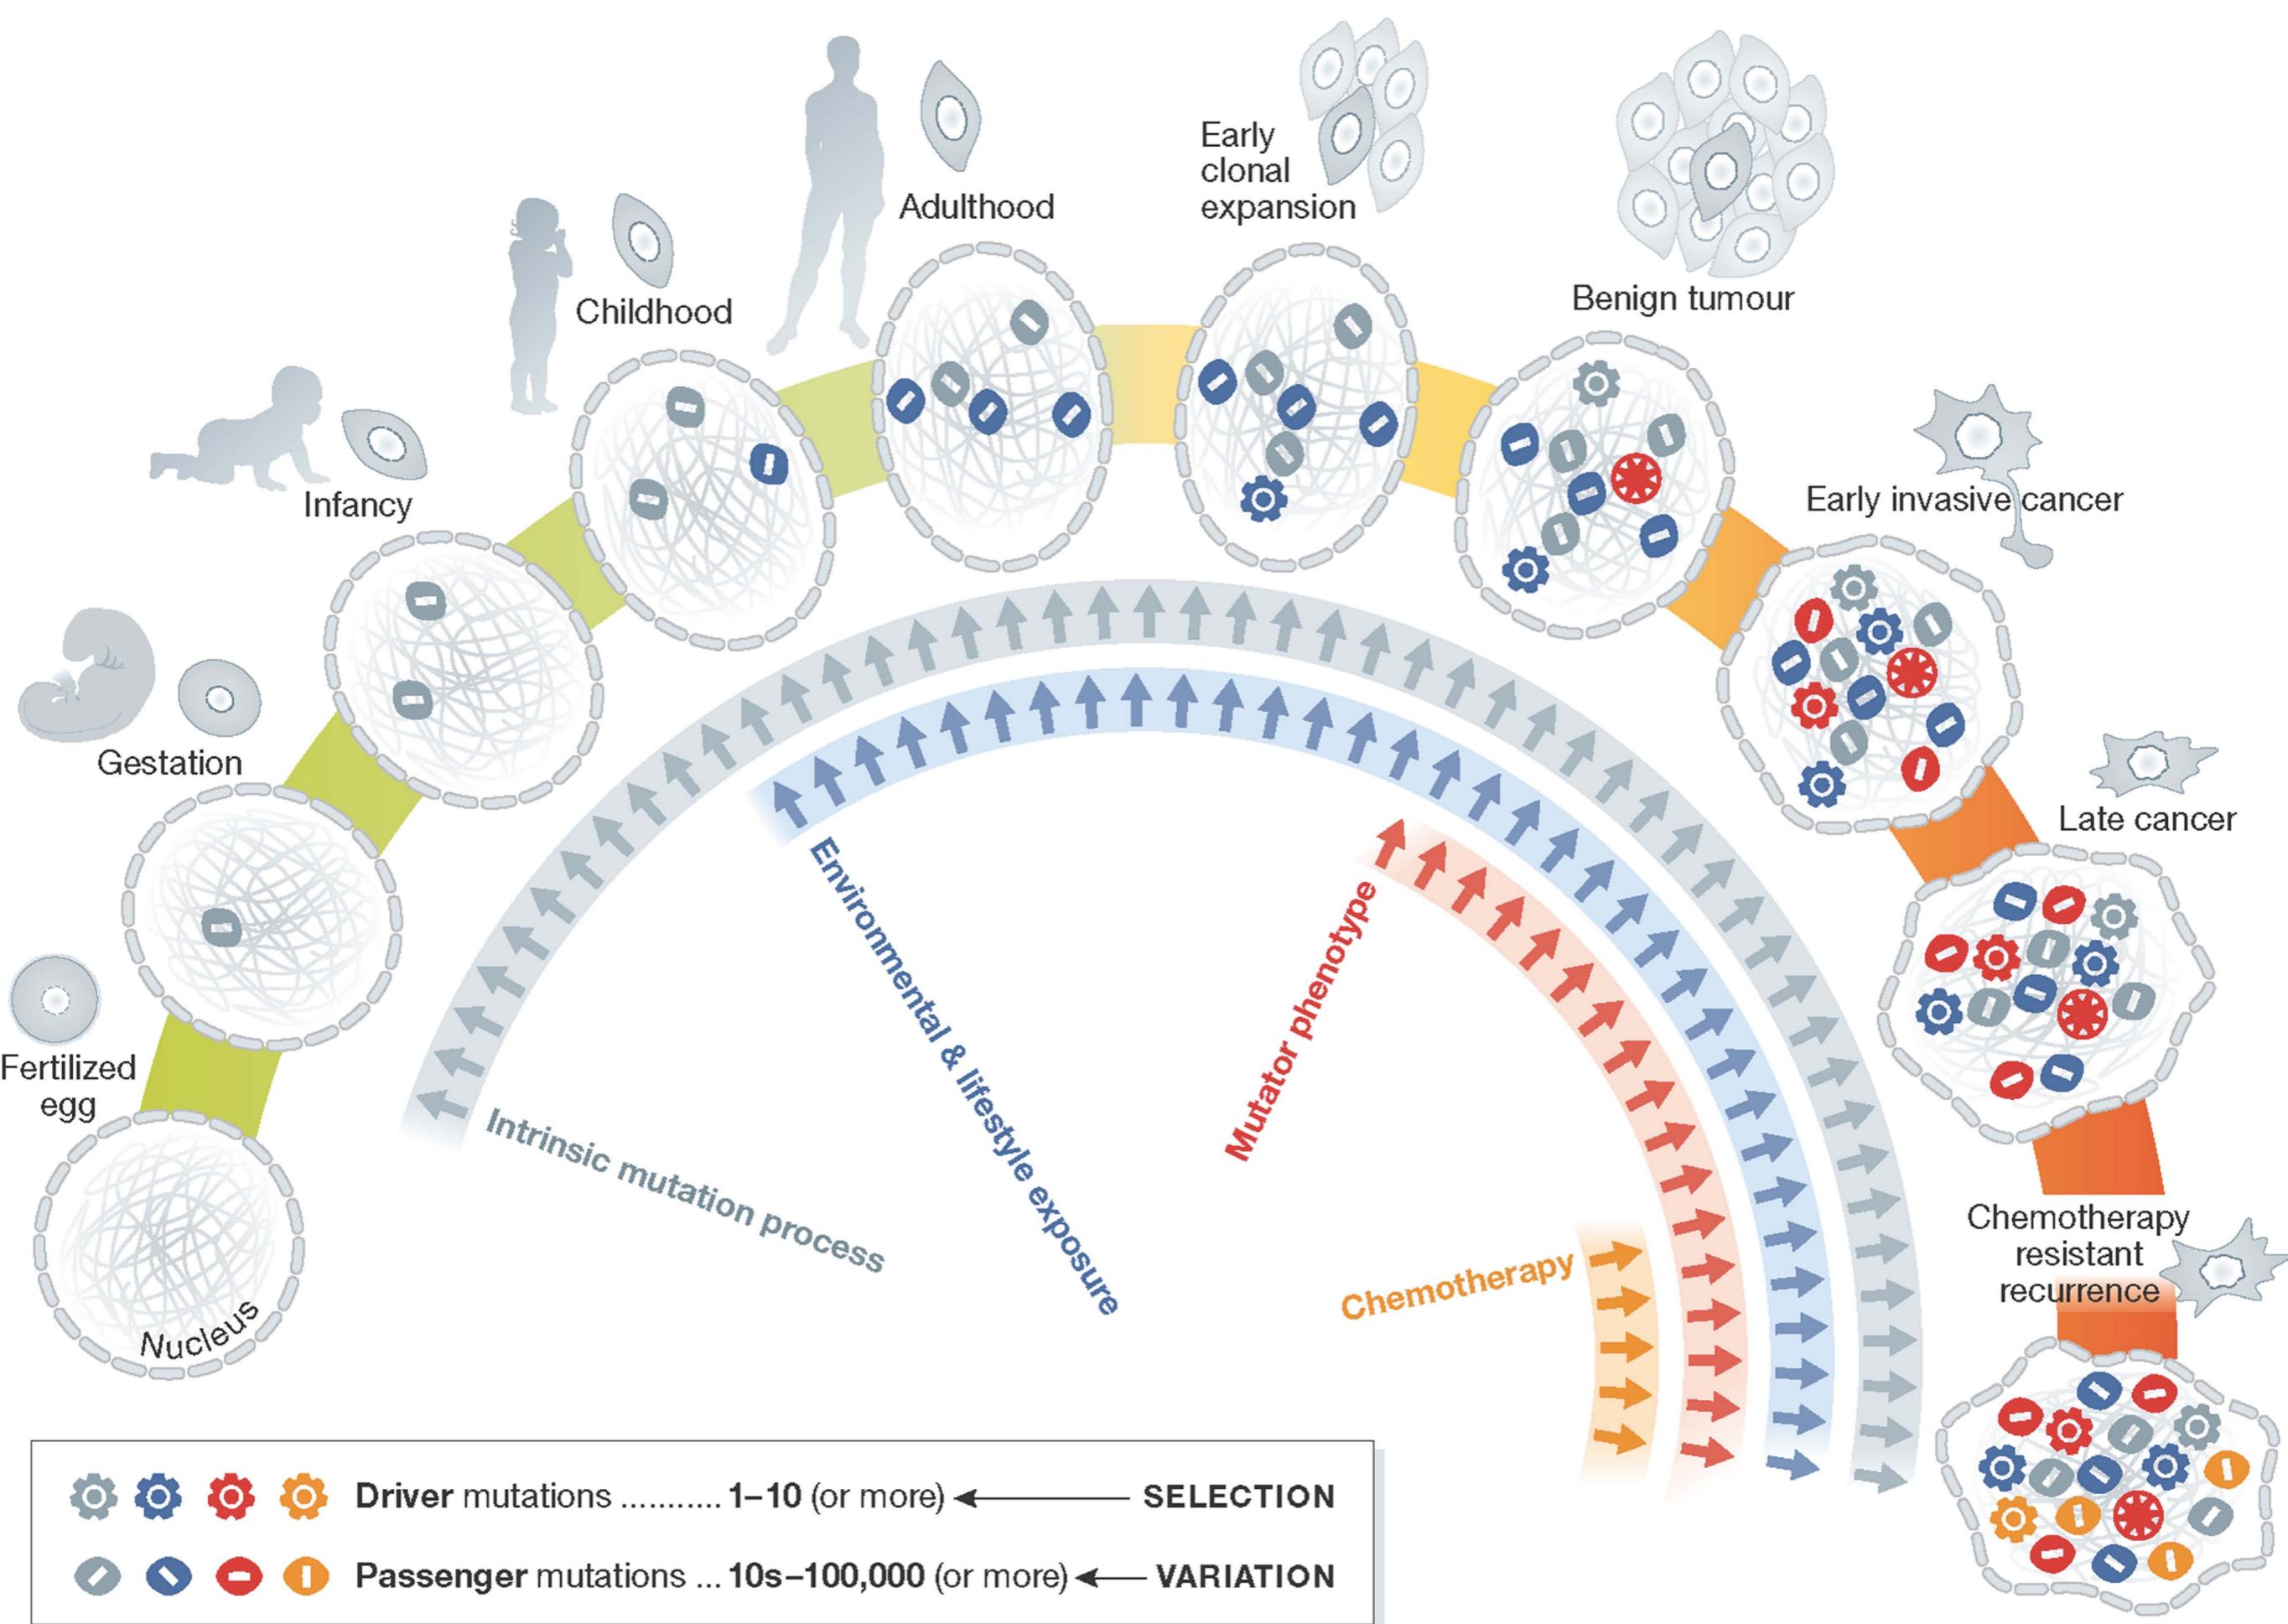

Number of somatic mutations in representative human cancers, detected by genome-wide sequencing studies

Genomic approaches can identify the genes most commonly mutated in cancer

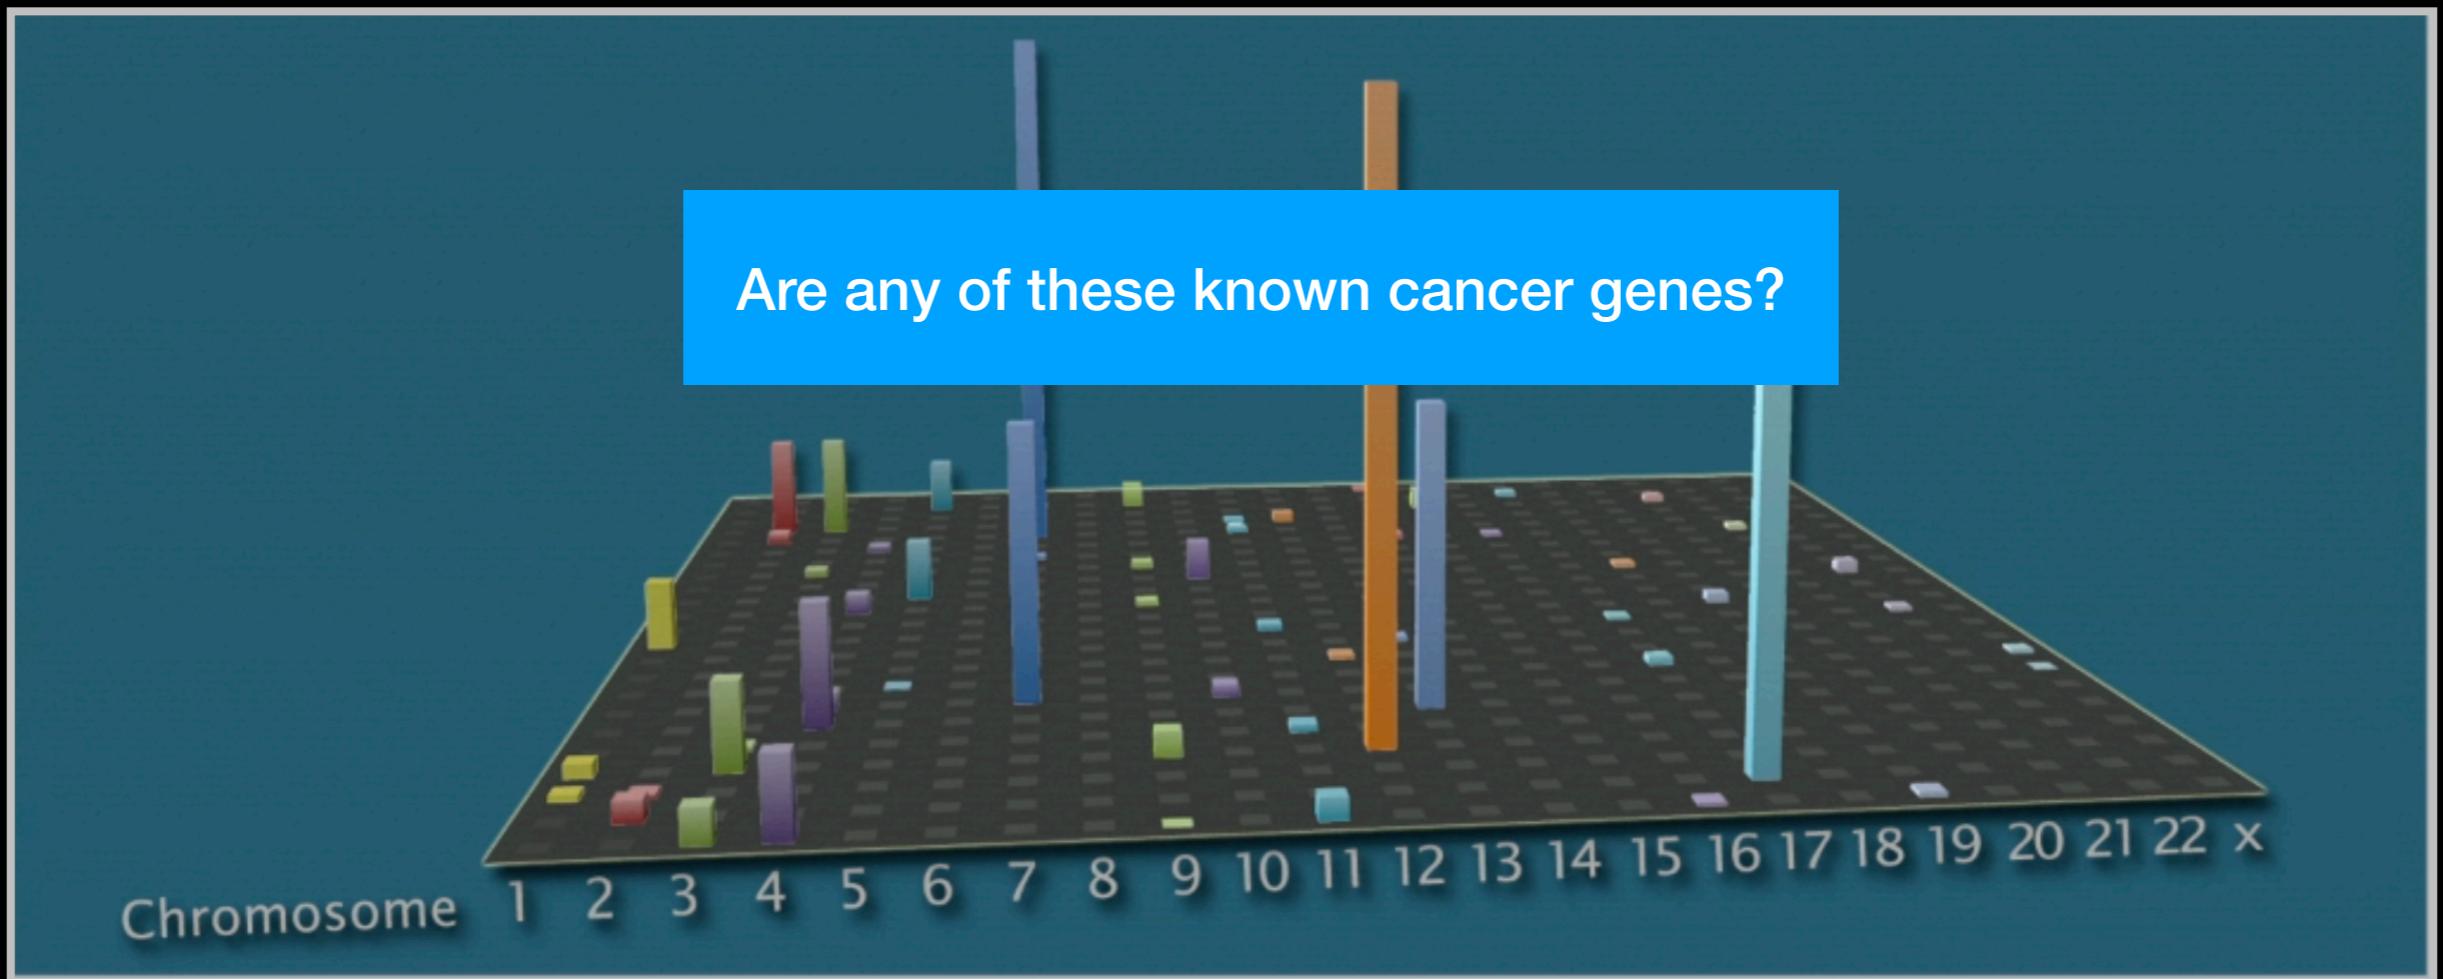

Arrange all genes in a matrix, ordered by chromosomes

Identifying genes most commonly mutated in cancer

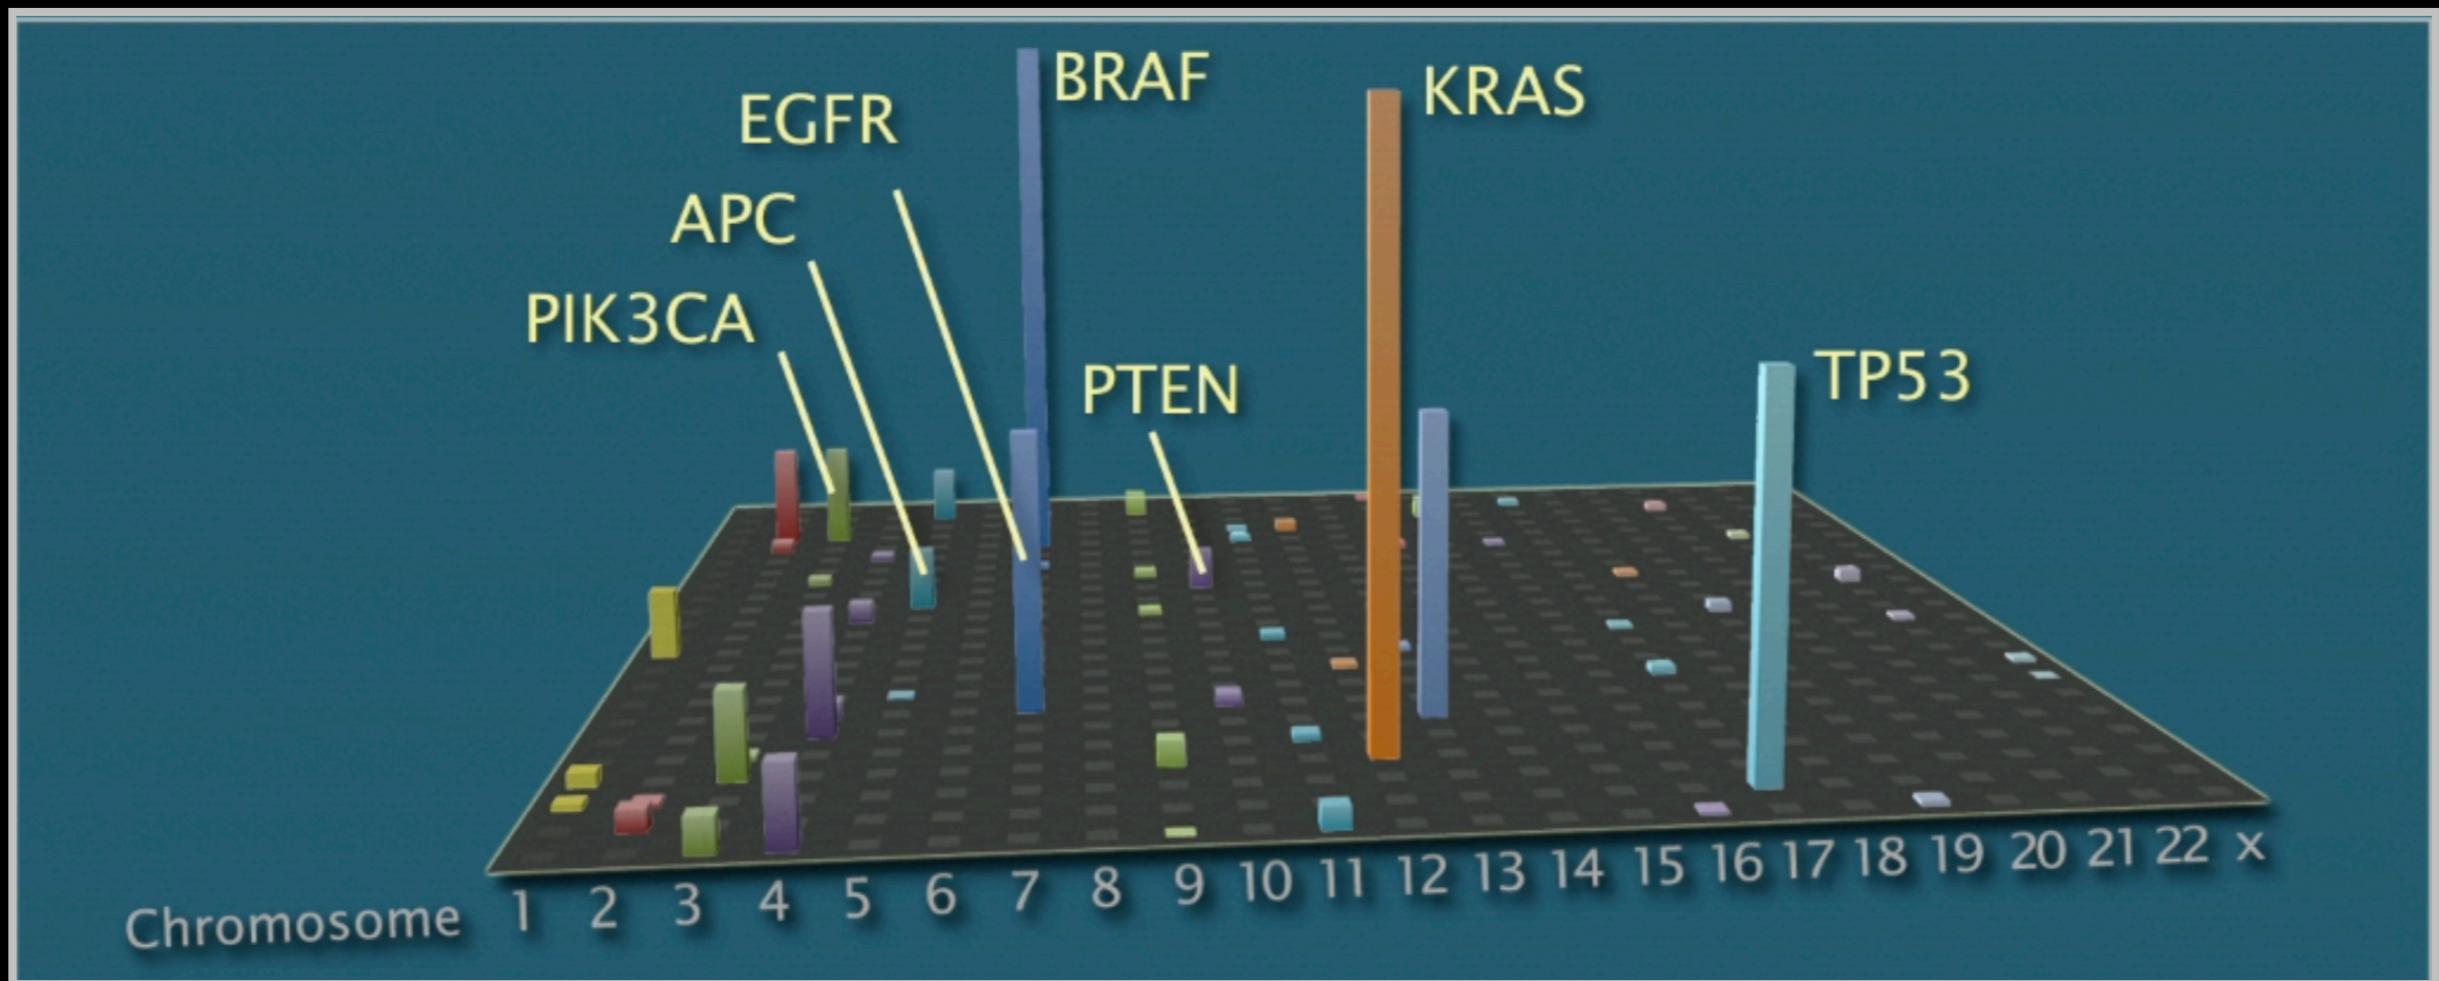

Add all data together to see which genes are most often mutated

Identifying genes most commonly mutated in cancer

Add all data together to see which genes are most often mutated

Identifying genes most commonly mutated in cancer

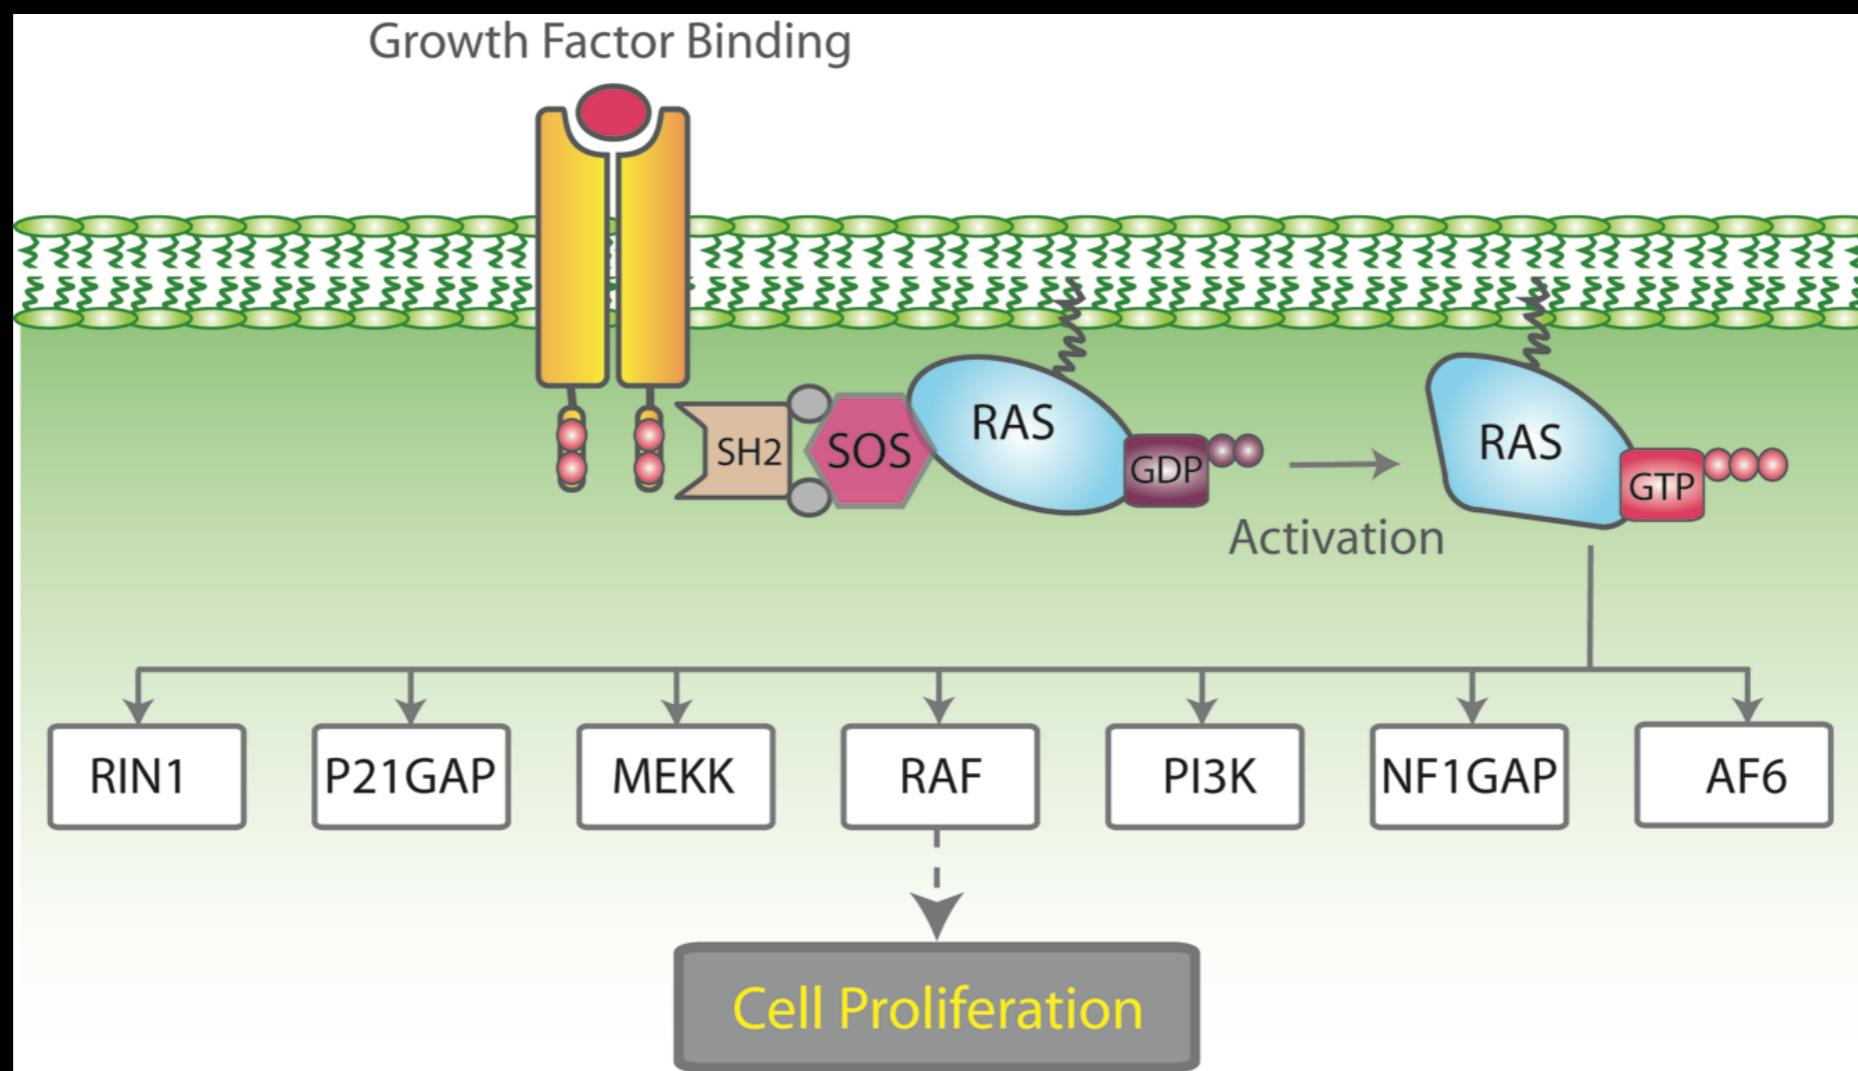

Many are famous proto-oncogenes, many others are new cancer genes!

Three Main Types of Cancer Genes:

- **Oncogenes**, such as **Ras**, normally function to accelerate cell division and growth. They can be mutated to act like stuck gas pedals.
- **Tumor suppressor genes**, such as **p53** normal act like breaks. Mutations can cause these breaks to fail.
- **DNA repair genes**, such as **BRCA1 & 2**, normally function to fix minor damage to DNA when it replicates. When these genes are mutated, DNA damage can accumulate and lead to cancer.

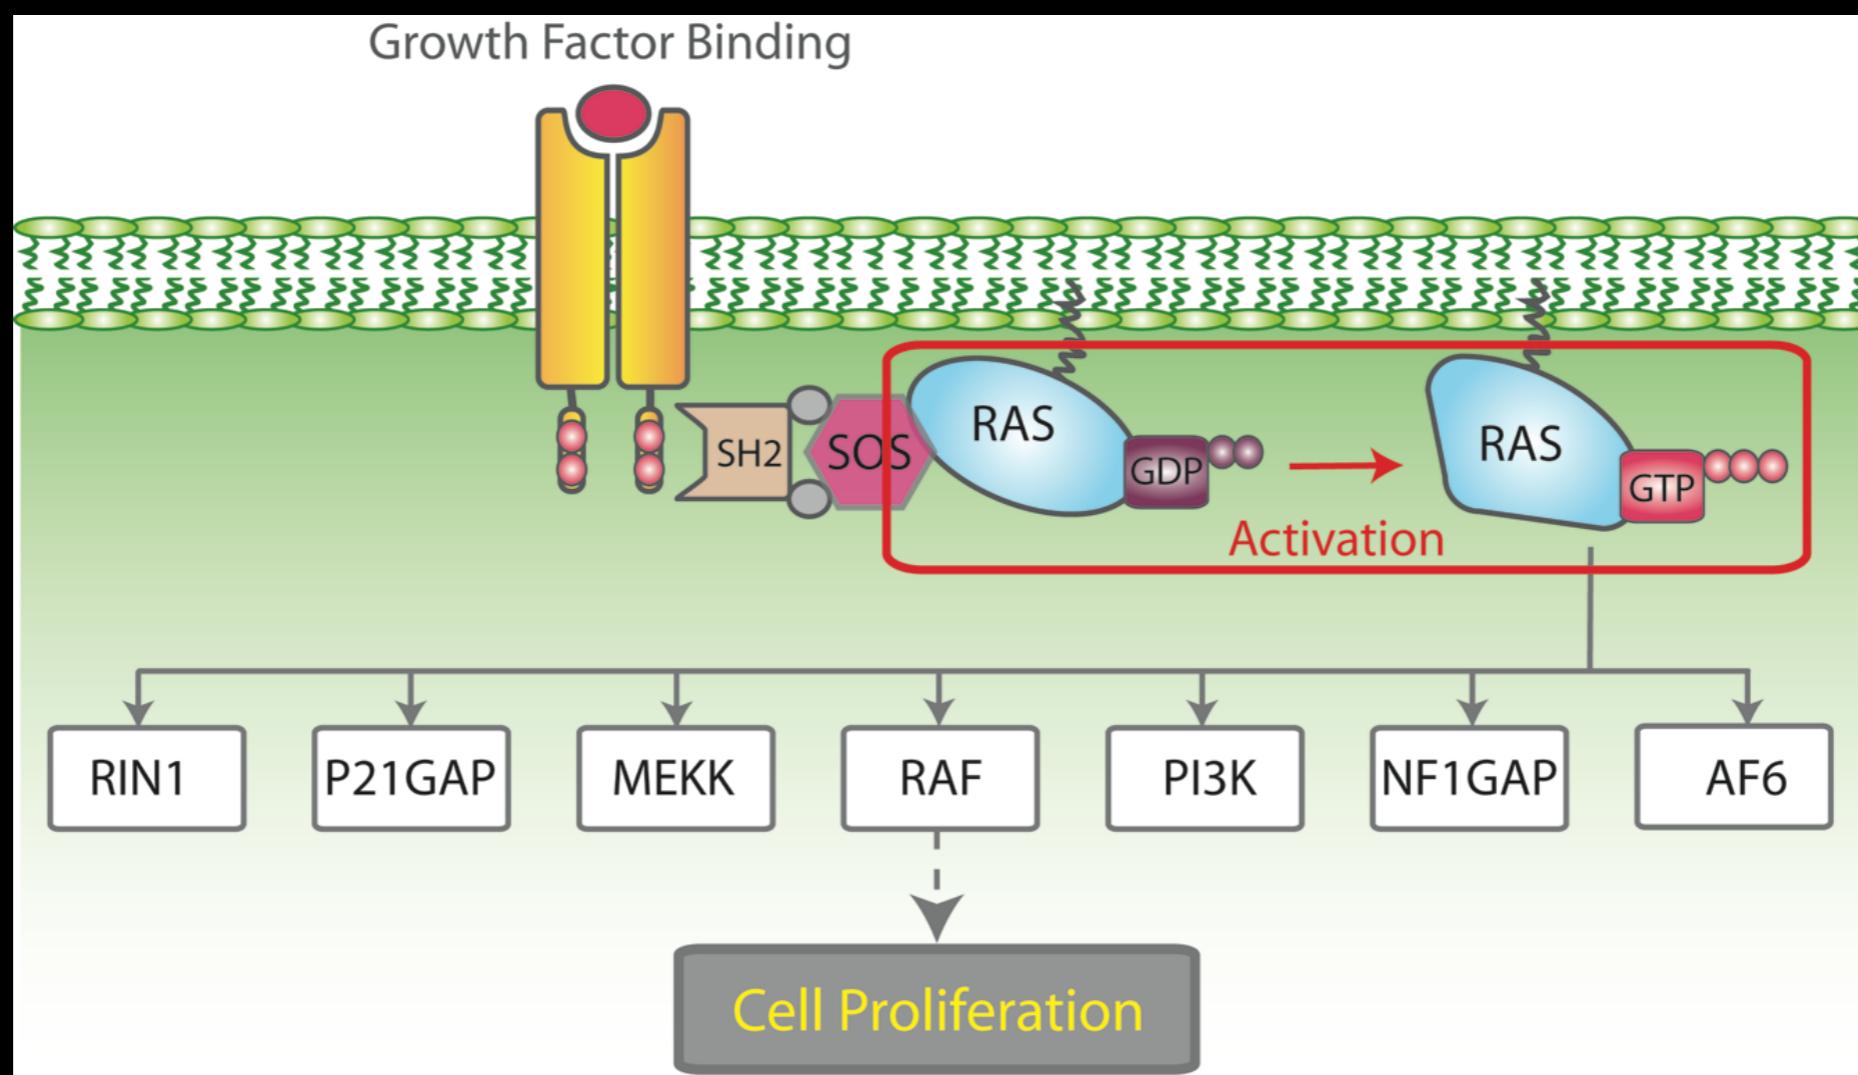

Cell growth and survival genes

Many participate in signaling pathways that promote cell proliferation
(E.G. EGFR, Ras, BRAF, MEK etc.)

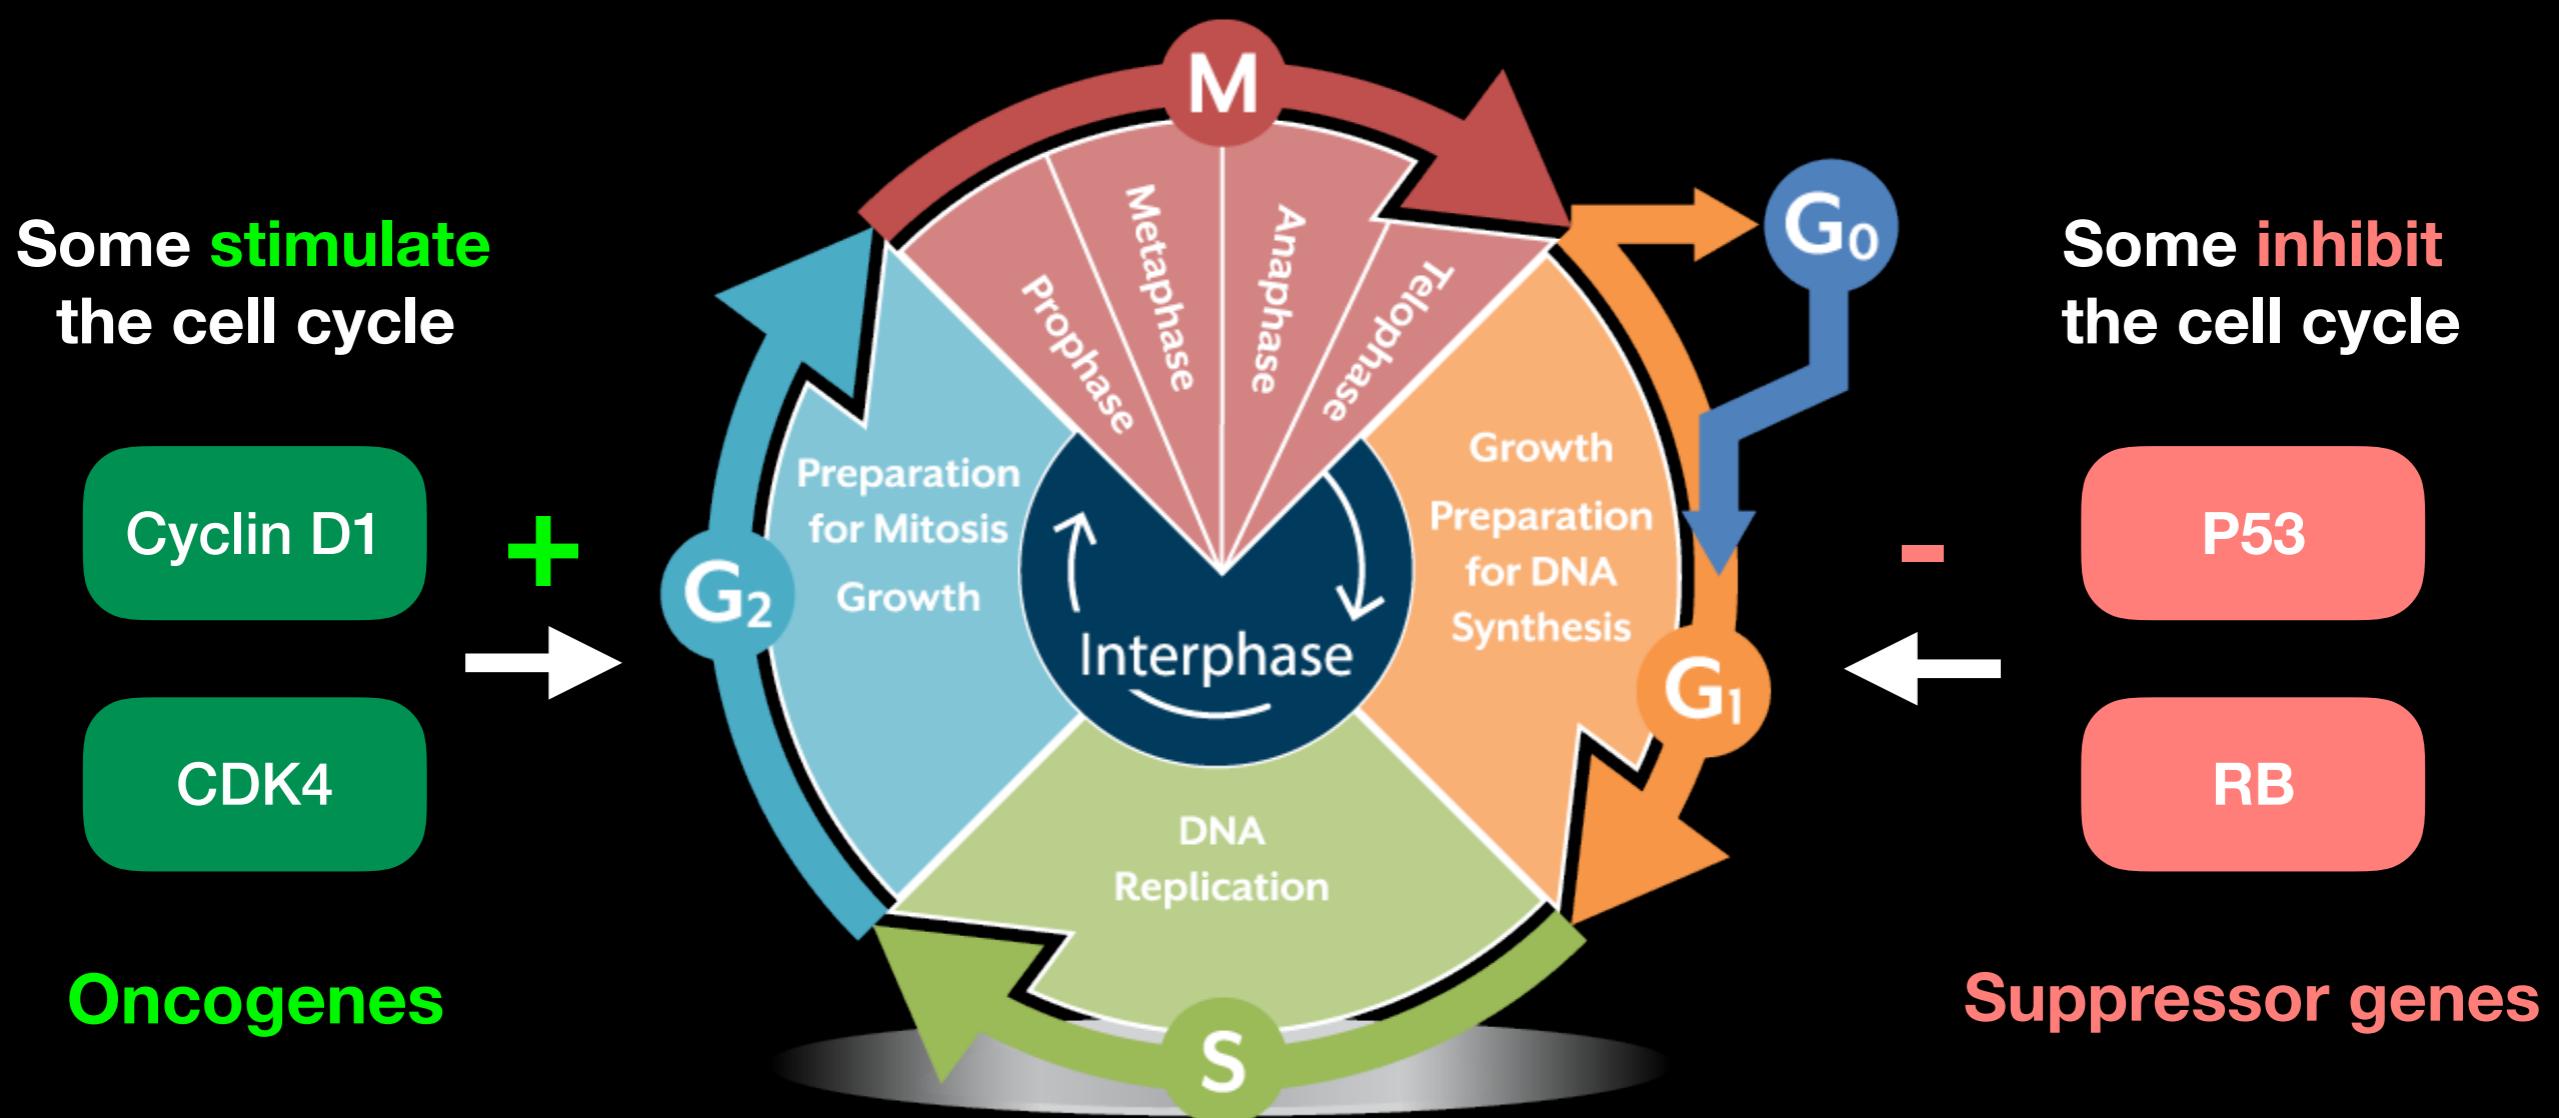

Cell growth and survival genes

Many participate in signaling pathways that promote cell proliferation
(E.G. EGFR, Ras, BRAF, MEK etc.)

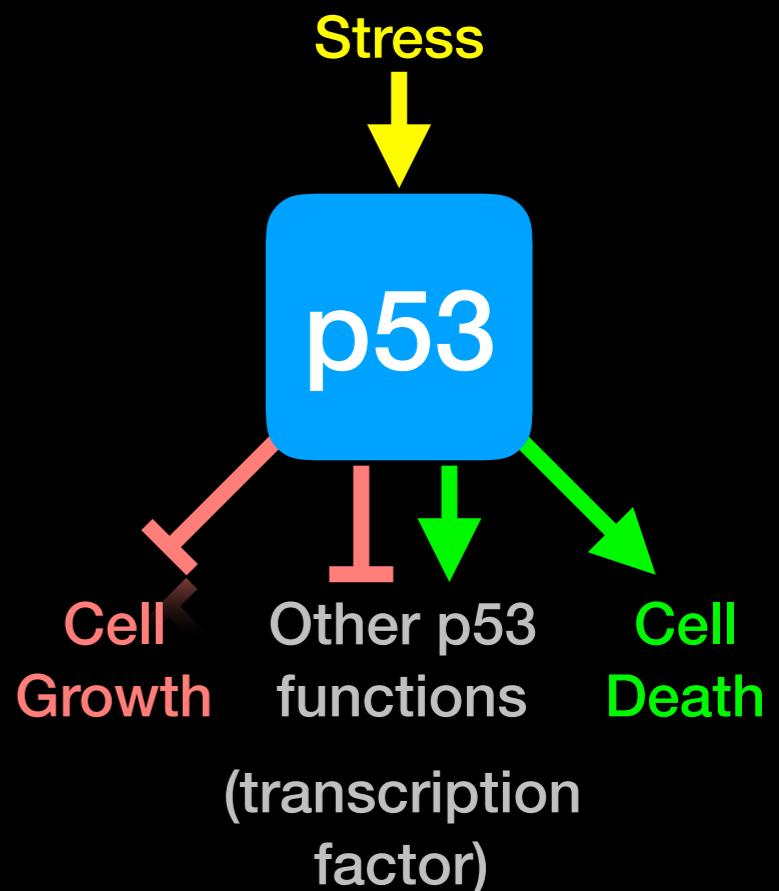

Regulators of Cell Cycle and Cell Death

p53 Regulates Cell Division

Probably the most famous cancer gene that is mutated in about half of all tumors. Often called the '*guardian of the genome*'

- p53 normally shuts down cell division when a cell is stressed (e.g. by DNA damage)
- When DNA is damaged, p53 activates genes that stop cell growth or trigger the cell to die.
- Thus, p53 guards against changes to cells that might lead to tumor formation.
- It appears necessary to inactivate p53 to develop many forms of cancer.

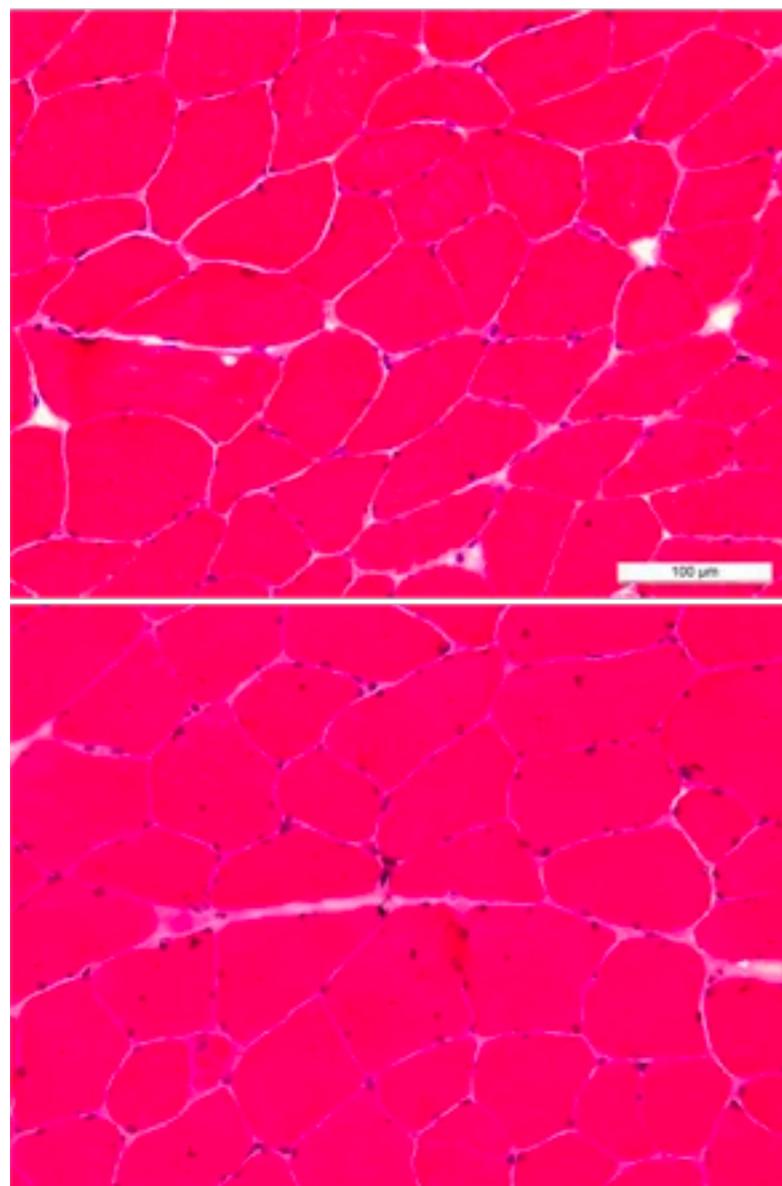

Hands-on time!
